ORGANIC CHEMISTRY

COURSE OUTLINE:

- Definition of organic Chemistry
- Properties of organic compounds
- Functional groups of organic compounds
- Molecular empirical structural formulae
- Homologous series (Groups of organic compounds)
- Alkanes
- Alkener > Hydro carbons
- Alkynes
- Alkyl halides (Halogeno alkanes)
- > Alcohols
- > Ethers
- > Phenols
- Benzene
 - ✓ Methy/Benzene
 - ✓ Nitrobenzene

⁻ Aromatics

- ✓ Chlorobenzene
- Carbons/compounds
 - ✓ Aldehydes (Alkanals)
 - ✓ Ketones (Alkanones)
- Carboxylic acids
 - ✓ Acidic halides (Alkanoy chlorides)
 - ✓ Amides
- Esters
- Amines
- Diazonium salts
- Applied organic chemistry
- Practical organic chemistry

Reference books:

Principles of Organic Chemistry A' level Chemistry – Ramsden.

INTRODUCTION:

Definition of Organic Chemistry:

Organic Chemistry is the Chemistry of Carbon and related elements. It does not involve inorganic compounds of carbon like CO_2 , $CO_3^{2-}s$, $HCO_3^{-}s$.

Organic Chemistry started when the first organic compounds were largely obtained from living things. This therefore makes carbon as the most abundant element in living organisms.

PROPERTIES OF ORGANIC COMPOUNDS:

Organic compounds are characterized by the following properties:

- They are made up of carbon and other elements like H₂, O₂, N₂, S, P and Cl₂.
- They are complex in structure e.g. some are made up of long chains of carbon, highly branched chain, rings of carbon.
- They exhibit isomerism a condition in which several structures can be written from one molecular formula.
- All organic compounds are bonded by covalent bonding.
- Most organic compounds undergo slower reactions.
- From the above properties, organic chemistry places a lot of interest in the behaviour of carbon.

Carbon as an element in organic chemistry:

C(6) = 2:4 1S²2S²2P² Electronic configuration

From the above configuration, carbon has got two principle equation numbers, a total of 6 electrons.

2 electrons in the S-orbital (inner energy level).

4 electrons in the 2^{nd} principle quantum number distributed as 2 in the S-orbital and 2 in P-orbital.

When carbon undergoes a chemical reaction, it uses all the four electrons in the P-quantum number which gives it a tetravalent.

Since bonding in organic compounds occurs in covalent bond (sharing electrons), it means each carbon atom should contribute four (2 pairs of electrons). Carbon then forms 4 covalent bonds by molecular mixing of orbitals a process known as Hybridization.

HYBRIDIZATION OF ORBITALS IN CARBON

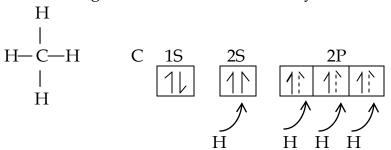

C(ground state-uncreative)

S	S	Р		
${}$	<u>~</u>	_	_	

When carbon atom is excited, one electron from the 2S – orbital is sent to the 2P giving in total four unpaired electrons which now become the tetravalent of carbon.

Bonding in carbon thereof involves the mixing of the S – and the P-orbitals.

(i) Formation of alkanes (Example methane). Bonding in alkanes involves 2SP³ hybridization.

(ii) Bonding in alkenes

In alkenes, bonding involves 2Ps hybridization.

(iii) Bonding in alkynes

2SP hybridization e.g. ethyne

i.e. 1 electron in 2S of each carbon atom combines to form a normal sigma bond while each hydrogen combines with each of the 2SP electron leaving 2 unpaired electrons in the 2P which will overlap to form 2π bonds.

$$H - C - C - H$$

$$H-C\equiv C-H$$

UNIQUE PROPERTIES OF CARBON

Carbon is generally a unique element and it displays the following properties:

- (i) If forms multiple bonds with other elements or itself. E.g.
 - double bond C = C (alkene); C = O (carbons)
 - triple bond $C \equiv C$ (alkynes); $C \equiv N$ (Nitrates)

Carbon forms up to 4 covalent bonds and this is always exhibited in all its compounds.

$$-\stackrel{\mid}{C} -C\equiv C -C\equiv N.$$

Carbon forms long chain compounds a process known as catenation, e.g. - C - C - C - C -.

Carbon rings and branded compounds.

FUNCTIONAL GROUP:

Is an atom of groups of atoms in an organic compound that determines the chemical properties of that compound.

Most of the chemical reactions of organic compounds are determined by their functional group.

Families of organic compounds known as homologous series are also determined

by functional group.

No.	Homologous series	Functional group	Examples
1.	(class) Alkanes $C_n H_{2n+2}$ (R - H)	- C - C - (Carbon single bond)	H ₄ (Methane)
2.	Alkenes (C_nH_{2n})	$-\overset{\downarrow}{C} = \overset{\downarrow}{C} - \text{(Carbon double bond)}$	C_2H_4 (Ethene)
3.	Alkynes $(C_n H_{2n+2})$	$-C \equiv C - (Carbon triple bond)$	C_2H_2 (Ethyne)
4.	Alkyl halides/halogenal alkaner (R-x) $C_nH_{2n+1}X$ Where X is a halogen e.g. Cl_2 , Br.	Halogen(X)	C_2H_5Cl (Chloro ethane)
5.	Alkanals (alcohols) $(C_n H_{2n+1} OH)(R - OH)$	Hydroxyl group (-OH)	C_3H_7OH (Propanol)
6.	Ethers (R-OR)	- O - (Oxygen)	C_2H_6O H H H H H H H H H H H H H H (di methyl) (ether of methoxyl)
7.	Carbons/Compounds (i) Alkanals (aldehydes)	O - - C - H (Carbony/Carbon & H ₂)	C_2H_4 H O H C
	(ii) Alkanones (Ketone) O II R - C - R	O - - C - (Carbony/Carbon)	C_3H_6O (Propanone) H H H H H H O H O H

8.	Carboxylic acid	Q	$C_2H_4O_2(Ethanoic\ acid)$
	R - COOH	- C - O - H	
		Carboxylic acid group	H O H - C - C - O - H
			H
9.	Esters (ROOR)	O	$C_3H_6O_2(Methyl\ ethanoate)$
		O - -C-O-	НО Н
		/	H O H H - C - C - O - C - H
			н н н
10.	Nitro compound	$-NO_2(Nitro\ group)$	$C_2H_4NO_2(Nitro\ ethane)$
	R - <i>NO</i> ₂		H
			H H H - C - C - NO ₂
			H H
11.	Nitriles (Cyanohydrins)	$-C \equiv N(Nitrile\ group)$	Ethanitrile C_2H_3N
	R - C≡N		Ħ
			$H - C - C \equiv N$
			Н
12.	(Acido halides)	O - C - X	$C_2H_3O_4Cl$
	$ \cap$	− C - X	Η Q
	R - CO - X		H - C - C - X
			Ĥ
			(Ethanoyl)
13.	Amides	O	$C_2H_5 - ON$
	P	- C - NH ₂	$H O$ $H - C - C NH_2$
	$R - C - NH_2$	(Amide group)	$H - C - C NH_2$
			H
			(Ethanimide)
14.	Amines	$-NH_2$ (Amino group)	부
	$(R-NH_2)$		H - C - NH ₂
			Ĥ
			CH_5N (Methyl amine)

EMPIRICAL MOLECULAR AND STRUCTURAL FORMULAE

Empirical formula is the simplest formula which expresses the ratio of the number of atoms present in a molecular or compound. E.g.

A certain organic compound has 39.13% by mass Carbon 52.23%, Oxygen and the rest hydrogen, determine its empirical formula.

$$39.13 + 52.23$$

$$100 - 91.36 = 8.64$$

Element	C	Н	O		
Percentage composition	39.13	8.64	52.23		
Composition	<u>39.13</u>	<u>8.64</u>	<u>52.23</u>		
Rfm	12	1	16		
Number of moles	3.2608	8.64	3.2644		
Divide by smallest	3.2608	<u>8.64</u>	3.2644		
	3.2608	3.2608	3.2608		
Mole ratio	1 x 2	2.6×2	1 x 2	$1 \times 3 2.6 \times 3$	1×3
	1	5.3	1	$C_3H_8O_3$	

[∴] Empirical formula = $C_2H_5O_2$.

Molecular formula expresses the true or actual number of each atom present in 1mole of a compound. It is also a multiple of an empirical formular.

$$\frac{Molecular\ formula\ mass}{Empirical\ formula\ mass} = n\ n = simple\ whole\ number.$$

Molecular formula = [Empirical formula].

MOLECULAR FORMULA MASSES:

They can be determined from;

(i) Vapour density:

When a compound is vapourized and weighed, its mass is twice the molecular formula mass.

$$2 \times V.P = MFM.$$

- (ii) Rates of diffusion (Graham's law) $MFM_A = \left(\frac{R_A}{R_B}\right)^2 \times MFM_B$
- (iii) Ideal gas equation $PV = nRT; PV = \frac{mRT}{mR}$ $Mr = \frac{mRT}{PV}$

GASEOUS HYDROCARBONS (EUDIOMETRY)

Eudiometry is a technique used to determine molecular formula of gaseous hydrocarbons.

When a gaseous hydrocarbon is exploded with excess oxygen, it readily burns forming $CO_{2 \ and} \ H_2O$ as the only product.

If the gases are passed over an alkali e.g. (KOH or NaOH), all the CO₂ formed is absorbed and the diminution (reduction) in the volume of the gases is due to CO₂.

The residual gas at that point will now be excess O_2 .

The volume of H₂O formed is regarded as negligible.

$$C_X H_Y(g) + \frac{x+y}{4} O_2(g) \longrightarrow XCO_2(g) + \frac{x}{2} H_2O_{(l)}$$

From the above equation, everyone mole of a hydrocarbon is equivalent to X moles of \mathcal{CO}_2 produced.

Similar when the volumes are related, the volume at CO_2 is equivalent to (X) x volume of CO_2 produced.

X(Volume of HC) = Volume of CO₂ produced.

Then the volume of O_2 used can also be related to the volume of the hydrocarbon by volume of;

Oxygen used =
$$\left(\frac{x+y}{4}\right)$$
 (Volume of hydrocarbon).

Example:

 $15cm^3$ of a gaseous hydrocarbon were exploded with $105cm^3$ of oxygen in a sealed vessel after cooling, the residual volume occupies $75cm^3$. On addition of caustic potash, there was a final diminution/decrease of volume to $30cm^3$. Determine the molecular mass of a hydrocarbon.

Let the hydrocarbon be $C_x H_y$.

$$C_x H_{y(g)} + \left(\frac{x+y}{4}\right) O_{2(g)} \longrightarrow XCO_{2(g)} + \frac{y}{2} H_2 O_{(l)}$$

Volume of O_2 used = $105 - 30 = 75cm^3$ Volume of CO_2 produced = $75 - 30 = 45cm^3$ C_xH_y = volume of CO_2 produced. = 45.

$$\frac{45}{15} = 3.$$

$$(Volume \ of \ HC) \left(x + \frac{y}{4}\right) = Volume \ of \ O_2 used.$$

$$15 \left(3 + \frac{y}{4}\right) = 75$$

$$3 + \frac{y}{4} = 5$$

$$3 + \frac{y}{4} = 2$$

$$y = 8.$$

Molecular formula is C_3H_8 12 x 3 + 8 x 1 = 449.

DETERMINATION OF MOLECULAR FORMULA OF ORGANIC COMPOUND USING MASS OF $CO_{2 \text{ and }} H_2O$.

When an organic compound is burnt, the masses of the products, carbon dioxide and H₂O together with the initial mass of the organic compound can be used to determine the molecular formula.

Example:

0.464g of an organic compound Q when burnt gave 1.32g of CO₂, 0.315g of H₂O. When 0.2325g of Q were separately burnt, 7.08 cm³ of N₂ gas at s.t.p was produced. Determine the molecular formula of Q and draw its structure. Vapour density = 46.5.

Organic cpd +
$$O_2$$
 \longrightarrow CO_2 + H_2O
12g of C 44g of CO_2
2g of H 18g of H_2O .

12g of carbon produces 44g of CO₂. Xg of carbon produce 1.32g of CO₂.

$$\left(\frac{12}{44} \times 1.32\right) g$$
 of carbon inorganic compound.
= 0.36g.

Percentage of carbon =
$$\frac{0.36}{0.464} \times 100$$

= 77.6%

2g of H₂ in Q produces 18g of H₂O. y of H₂ in Q produces 0.315g of H₂O. y = $\left(\frac{2}{18} \times 0.315\right) g$ of H₂ = 0.035g.

Percentage of H in Q =
$$\frac{0.035}{0.464} x 100$$

= 7.5%

Mass of Nitrogen =
$$0.36 + 0.035 = 0.395$$

 $0.464 - 0.395$
= $0.069g$ of N₂.

Percentage of
$$N_2 = 77.6 + 7.5 = 85.1g$$

 $(100 - 85.1)$
 $= 14.9\%$

1 moleof a gas contains 22400cm^3 at s.t.p. Xmoles of N_2 contains 7.08cm^3 .

$$\frac{7.08}{22400} = 3.16 \times 10^{-4}$$
 moles.

0.2325g of Q produces 3.16×10^{-4} moles of N_2 . Xg of Q produced by 1mole of N_2 .

Elements	C	Н	N
Percentage composition	776.	7.5	14.9
Relative atoms	77.6	7.5	14.9
	12	1	14
Moles	6.47	7.5	1.06
Simple ratio	6.47	7.5	1.06
omple ratio	1.06	1.06	1.06
Simple ratio	6	7	1

Empirical formula
$$C_6H_7N$$

 $(C_6H_7N)n = 46.5 \times 2$
 $n(12 \times 6) + 7 \times 1 + 14 = 93$
 $93n = 93$
 $n = 1$.

Molecular formula = C_6H_7N

Phenyl-amine.

STRUCTURAL FORMULA

It shows the different atoms and how they are connected in one molecule of a compound e.g.

1. Ethane structure.

$$H$$
 H H H H H H H H H

2. Nitrobenzene ($C_6H_5NO_2$).

3. Propane (C_3H_8)

4. But-2-end (C_4H_8)

5. Buta-3-diene

ORGANIC COMPOUNDS

Organic compounds are generally classified according to the functional groups they do have and its very important that all the organic compounds are given names.

NOMENCLATURE OF ORGANIC COMPOUNDS

Naming of organic compounds follows a strict system of nomenclature where names are assigned.

NAMING OF HYDRO CARBONS

They are named using "stem" names that indicate the alkyl groups. E.g.

Alkyl group:		Name:
\pm_{CH_3}	1	Methyl
$\pm_{CH_2CH_3}$	2	Ethyl
$+_{CH_2CH_2CH_3}$	3	Propyl
$\underline{+}_{CH_2CH_2CH_2CH_3}$	4	Butyl
$-C_6H_5$ or \bigcirc	> -6	Phenyl

RULES GOVERNING NOMENCLATURE (Guidelines)

- (i) Hydrocarbons are named as derivatives of alkanes. Where the suffic-aneis added to the stem name.
- (ii) Always identify the longest continuous chain in the compound and this gives the parent name. Other things attached to that chain are regarded as branches. E.g.

(iii) Number – the carbon parent chain from one end to the other end giving the position of the branch the lowest number. E.g.

(iv) If there are more than one substituent branch, the numbering has to consider the lowest sum of the positions. E.g.

R - L - sum of branches =
$$4 + 5 = 9$$
.
L - R, sum of branches = $2 + 3$ selected.
= 5

The sum of the locants moving from left to right is the lowest and therefore it is preferred.

- (v) All the positions of the locants are identified and they are put as prefix separated with a (-) in the branch. E.g.
 - 2 methyl
 - 3 methyl
- (vi) When there are more than one substituent, the following is noted:
 - (a) Similar substituents are given a prefix di 2, tri 3, tetra 4 ---- and their locants are also indicated before the prefix but the locant separated by a comma(,). E.g. 2, 3-dimethyl.

The numerical order of the locants is followed.

$$CH_2 CH_3$$

$$H_3C CH - CH CH_2 CH_2 CH_3 \quad \text{hex - 6 carbon atoms.}$$

$$CH_3$$

$$3 - Ethyl$$

$$2 - Methyl$$

The alphabets in the beginning letter of the names of the substituent has got to be followed.

(vii) The last name to be written is the parent name which indicates the number of carbon atoms in the chain.

3, 3-dimethyl -5-ethyl heptanes.

If a multiple bond (triple or double bond) is present, then the longest chain identified must involve the (double or triple) bond.

The multiple bond must be given the lowest number within the stem name.

$$H_3C$$
 CH_2 $CH = C - CH_2CH_3$

$$CH_2$$

$$CH_2$$

$$CH_2$$

$$CH_7$$

4-ethyl heft-3-ene.

(viii) When there are other functional groups, their positions, names are indicated. E.g. Halogen (*Cl*, F, Br, I)= Chloro, Fluoro, Bromo, Iodo.

$$OH = (alcohol) - Ol$$

$$C = C$$
 (double bond) – ene

 $C \equiv C$ (triple bond) – yne.

$$C$$
 (Ketone) – one $-NH_2$ (amine) – amine.

(ix) VOWEL/CONSONANT RULE

When naming a compound where a locant is included within the stem name, the two letters close to the locant must be a vowel and a consonant and not all vowels or all consonants. E.g.

 $CH_3 CH = CHCH = CH_2 Penta - 1, 3-diene.$

HOCH₂CH₂ OH Ethane-1, 2-diol.

HOOC.COOH Ethane-1, 2-dioc acid.

CH₃COOH Ethanoic acid.

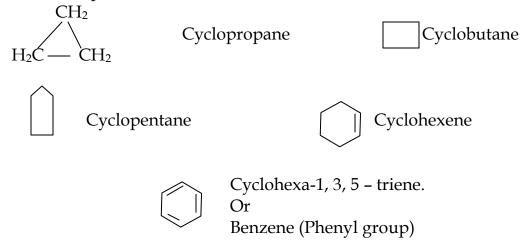

(x) When naming compounds with very many functional groups (poly functional compounds), the functional groups are assigned an order depending of the seniority order and this order is the carboxylic acid, carbonyl, cyanide, ketone, alcohol, amines, double bond, triple bond, nitro group and halogen.

$$NH_2$$
 $CH_3CH - CH CH = CH_2$
 Cl 4-chloro-3-amino pentene.

$$H_2C = CHCH_2CH_2C \equiv CH$$

Hexane-5-yne.

For the case of cyclic compounds (ringed compounds), the prefix "cyclo) is added to the parent alkane name.

STRUCTURES OF ORGANIC COMPOUNDS FROM NAMES:

Structures can be written from the names.

Example:

Butane

2-Methyl propane.

5-methyl heft-3-ene.

$$CH_3$$

 H_3C CH_2 CH = CH $CHCH_2$ CH_3

3, 4-dimethyl pentanol.

4, 5-dimethyl hex-2-yne.

H
H
H-C-H
H
H-C-C

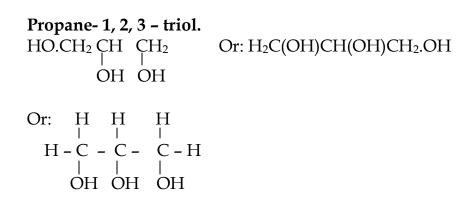

$$=$$
C-
C-
C-
H
H
H
H-C-H
H
H
H
H
H
H

Ethane-1, 2 - diol

Phenyl methanol

2-phenyl ethanol

2, 2 -dimethyl propane

International Union of Pure and Applied Chemistry.

N.B: Name organic compounds should always consider the IUPAC system. Where names and systematically written and this is the most universally known way of naming. However, trivial names may be found in a number of books and these should not be used for exam purposes.

E.g. CH≡CH (Ethyne) = (Acetylene) trivial name. CH₃CH₂CH₂OH Propanol = (Propyl alcohol) trivial name.

ISOMERISM

This is the existence of compounds with the same molecular formula but different structural formulae. These compounds are known as **Isomers**.

Types of isomerism

There are two types of isomerism with a number of subtypes.

1. Structural isomerism

The type of isomerism where compounds differ in the arrangement of atoms within the molecule i.e. isomers under structural isomerism differ in the carbon skeleton.

2. Stereo isomerism

Type of isomerism where compounds of the same molecular formula and structural formula differ in the spatial arrangement of atoms.

STRUCTURAL ISOMERISM

Structural isomers can be further subdivided into:

(i) Chain structural isomerism

This is where compounds differ in the arrangement of carbon atoms in a molecule.

Note: The position of the functional group in the chain must remain the same.

E.g.
$$(C_4H_{10})$$

H₃C CH₂ CH₂ CH₃*n*-Butene

H₃C CH CH₃ 2-methyl (propane).

 C_5H_{12}

H₃C CH₂ CH₂ CH₂ CH₃ *n*- pentane

$$H_3C$$
 CH_2 CH CH_3 3-methyl (butane) CH_3

(ii) Functional isomerism

Type of isomerism where the isomers differ by the functional group. Such isomers also differ in both physical and chemical properties. E.g. Alcohols.

- Ethers are isomeric.

 C_2H_6O

H₃C CH₂ OH Ethanol.

H₃COCH₃ Dimethy ether (methoxy ethane)

- Alkenes and cyclicalkanes

$$(C_3H_6)$$

 $H_3C CH = CH_2$ Propane

- Carboxylic acids and esters.

$$C_4H_8O_2$$

H₃C CH₂ CH₂ COOH Butanoic acid

(iii) Positional isomerism

Type of isomerism where the compounds with the same molecular formula differ in position of the functional group within the same carbon skeleton.

- (C₃H₇OH)

H₃C CH₂ CH₂OH Propan-1-Ol

H₃C CH CH₃ Propan-2-Ol OH

- C₄H₈

 $H_3C CH_2 = CH_2 CH_3$ But-2-ene $H_2C = CH CH_2 CH_3$ But-1-ene

- (C_4H_9Cl)

 H_3C CH CH CH - Cl Chloro butane H_3C CH(Cl) CH₂ CH₃ 2-Chloro butane

Question:

Write all the isomers of the compounds with molecular formula $C_5H_{12}O$.

1. H_3C CH₂ CH₂ CH₂ CH₂ OH n – Pent-1-ol

2. CH₃ CH₂ CH CH₃ Pentan-2-ol OH

3. CH₃ CH₂ CH CH₂ CH₃ Pentan-3-ol OH

4. CH₃ CH CH₂ CH₂ OH 3-methyl butanol CH₃

5.
$$CH_3$$
 CH_3 $C.CH_2$ OH 2, 2-dimethyl propanol CH_3

7. CH₃ CH₂ O CH₂ CH₂ CH₃ Ethoxy propane.

8. CH₃ O CH₂ CH₂ CH₂ CH₃ Methoxy butane.

Note: 1, 2, 3 are positional isomers.

4, 5, 6 are chain isomers.

7 and 8 are functional isomers.

STEREO-ISOMERISM

The compounds differ by spatial arrangement of atoms. There are two types i.e. geometrical steroisomerism and optical steroisomerism.

GEOMETRICAL STEROISOMERIM

Is where isomers have the same structural formula but differ in the spatial arrangement of the groups around a double bond.

Geometrical isomers arise as a result of a double bond which is planar and does not allow free rotation (restricted rotation) unlike a single carbon bond which freely allows rotation.

Geometrical isomers can therefore be;

(i) Cis-geometrical isomer.

Is when identical groups of atoms are on the same plane of the double bond.

(ii) Trans-geometrical isomer.

Is when identical atoms are rotated on opposite planes of the double bond.

But-2-ene

$$H$$
 CH_3 $C = C$ H Trans but-2-ene.

$$H$$
 $C = C$
 CH_3
Bis but-2-ene

1, 2-dichloro ethene.

Cis 1,2 dichloro ethene.

$$Cl = C$$
 H

Trans 1, 2 dichloro ethene

Butene-1, 4-dioc acid

Trans butane-1, 4-dioc acid.

$$H$$
 $C = C$ $COOH$

Cis butane- 1, 4-dioc acid

OPTICAL ISOMERISM

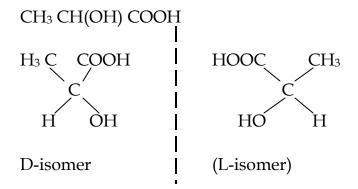

Type of isomerism that arises when two or more compounds with the same molecular or structural formula have got different optical properties in rotating the plane of polarized light.

The optical isomers are usually not super imposable onto each other and they have got marked differences in the physical and chemical properties.

For any optical isomers to exist, they must have a must have a mirror image of each other and rotating a plane of polarized light either to the right or to the left.

When an isomer rotates light to the right, it is known as **DEXTROROTARY** (D-isomer) (+ve isomer).

When it rotates light to the left, it is known as **LEVOROTARY** (L-isomer or -ve isomer). E.g. lactic acid (2-hydroxy propanoic acid).

CONDITIONS OF GEOMETRICAL ISOMERS

A compound must have asymmetrical centre. This is a centre joined by four different groups of atoms and that carbon centre is said to be asymmetric carbon. E.g. 2-methyl butan-2-ol (amyl alcohol).

Ways of writing organic compounds

- (i) Using carbon-carbon bonds. H₃C - CH₂ - CH₂ - CH₃ Butane. H₃C - CH = CH - CH₂ - CH₃ Pent-2-ene.
- (ii) Plainly illustrating atom. $CH_3 CH_2 CH_2 CH_3 Butane$. $CH_3 (CH_2)_2 CH_3$ Butane.
- (iii) Using the molecular formula.

 C_4H_8 Butene C_6H_6 Benzene $C_6H_5NO_2$ Nitrobenzene.

(iv) Using skeletal structure.

Note: No. (iv) is not commonly used at A' level.

ORGANIC REACTIONS

Generally most organic reactions are slow compared to inorganic reactions. At the same time, they yield different product depending on the conditions of reaction. When considering a particular organic reaction, conditions at which it takes place must be specified.

TYPES OF ORGANIC REACTIONS.

There are several types of organic reactions, categorized under different ways.

Bond breaking in organic reaction.

There are two ways in which bonds can be broken in organic reactions.

(a) **Heterolytic fission.**

Here an organic bond is broken and the resulting electrons within a broken bond are then taken up by one atom giving rise to ions. E.g.

(b) Homolytic fission

Type of bond breaking where by the resulting electrons in the broken bond are equally shared by the two atoms. This results into atoms with unpaired electrons which are called free radicals. E.g.

$$\underbrace{A}^{\bullet} + \underbrace{B}^{\bullet}$$
Free radicals

$$CH_3$$
 $+$ H Free radicals.

TYPES OF ORGANIC REACTIONS

1. ELECTROPHILLIC ADDITION REACTIONS

Electrophillic addition reactions are reactions in which an electrophille is added to a reacting substrate (molecule).

An electrophille is an electron seeking species or atoms. Electrophilles are usually positively charged. E.g. ⁺NO₃, ⁺Cl, ⁺CH₃.

Examples:

$$CH_2 = CH_2 + Cl - Cl$$
 \longrightarrow $Cl-CH_2 - CH_2 - Cl$.

2. ELECTROPHILLIC SUBSTITUTION REACTION.

Type of organic reaction where an electrophille is substituted by another electrophille.

3. SUBSTITUTION NUCLOEPHILLIC REACTIONS

Type of organic reaction where a nucleophille replaces another nucleophille in a reacting molecule.

A nucleophille is a species or group of atoms that seek for the positive centre of the reacting molecule. They either be negatively charged e.g. ${}^{\bullet}_{0}H$, ${}^{\bullet}Cl^{-}$, ${}^{\bullet}Br^{-}$ or neutral (uncharged). E.g. $H_{2}O^{\bullet}$, ${}^{\bullet}NH_{3}$.

All nucleophilles must have a lone pair of electrons.

$$CH_3 CH_2 CH_2 - Cl + {}^{\bullet}_0 H \longrightarrow CH_3 CH_2 CH_2 - OH + {}^{\bullet}Cl^-.$$

⁺CH₃ substitutes H⁺.

Nucleophillic substitution reactions can either be;

(i) Substitution nucleophillic biomelecular (SN₂). Here two molecules are involved in the rate determining step of the reaction.

OR:

- (ii) Substitution nucleophillic unimilecular (SN_1). Here only one molecule is involved in the rate determining step of the rnx.
- 4. Elimination reactions (E).

These are reactions where an atom is completely removed from the molecule. This always results into the formation of a double or multiple bond. E.g.

CI
CH₃ CH CH₃
$$\longrightarrow$$
 CH₂ = CH CH₃ + Cl⁻ + H⁺.

NOTE: Elimination reactions can also be biomolecular (E_2) or unimolecular (E_1) .

FACTORS THAT AFFECT ORGANIC REACTIONS.

(i) Conditions of temperature.

Temperature affects a number of organic reactions and therefore when writing those reactions, temperature has got to be specified.

(ii) Nature of the solvent.

The nature of the solvent used affects the type of organic reaction e.g. aqueous condition, organic solvent condition. E.g.

$$CH_3CH_2 - Cl + {}^-OH_{(aq)}$$
 heat $CH_3CH_2OH + {}^*Cl^-$

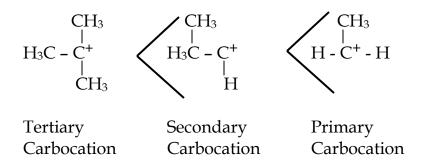

CH₃CH₂ - Cl +
$$\bar{o}H$$
 Ethanol
$$CH_3CH_2 - Cl + \bar{o}H$$
Heat

(iii) The structure of the reacting molecule.

The structure of the reacting molecule can affect the organic reaction in several ways like.

(a) Steric hindrance.

A condition in which the surrounding alkyl groups prevent a reagent from attaching the reaction centre e.g.

(b) Electronegativity

(c) Bond length.

Usually longer bonds are easily broken than the shorter ones. If a reaction proceeds by breaking a particular bond, a longer bond can then easily be broken than a smaller one.

MECHANISM OF REACTIONS

A mechanism of an organic reaction is an illustration by showing the flow of electrons from one centre to another. This flow is normally illustrated by means of curled arrows.

When a double headed arrow is used, it implies two electrons flowing i.e — and when a single headed arrow is used, it implies one electron i.e. — .

The arrow must always begin at the centre of the double bond where electrons are positioned and ends where electrons are deficient or it must begin at the centre of a lone pair of electrons. E.g.

Electron rich
(i)
$$CH_2 \stackrel{\longleftarrow}{=} CH_2$$
 Br^+ - Electron deficient centre.

(ii)
$$Cl \longrightarrow 2Cl^{\bullet}$$

(iii)
$$H_2O$$
 $+CH_2$ $--- CH_3$ $--- H_2O^+CH_2CH_3$

ALKANES

These are saturated hydrocarbons containing carbon and hydrogen elements only joined by a single covalent bond.

The open chain hydrocarbons (alkanes) have got a general formula of C_nH_{2n+2} where n=a whole number.

Functional group of all alkanes is a carbon - carbon "C- C" single bond where all the four valency electrons of carbon are involved in the bonding.

Examples:

$$n = 1$$

$$CH_4$$

$$H - C - H$$

$$H$$

$$Methane$$

$$H + H$$

$$H - C - C - H$$

$$H + H$$

NOMENCLATURE

Alkanes are named as saturated hydrocarbons by adding the suffix-ane on the stem name of the parent hydrocarbon.

The parent hydrocarbon indicates the number of carbon atoms.

Number of carbon atoms	Parent name	<u>Alkane</u>
n = 1	Meth	Methane
n = 2	Eth	Ethane
n = 3	Prop	Propane
n = 4	But	Butane
n = 5	Pent	Pentane
n = 6	Hex	Hexane

The branches on the parent chain must be indicated together with their positions.

For cyclic alkanes, the word cyclo has got to be written before the parent name.

H₃C CH₂ CH₂ CH₃

n - Butane.

H₃C CH₂ CH CH₃

2-methyl butane.

 H_3C – CH_3 – C – H – CH_2 – CH_3 3-isoprophyl pentane CH_3 — CH_3

Cyclo pentane

ISOMERISM IN ALKANES

Alkanes exhibit structural isomerism specifically chain isomerism where the isomers differ in the chain.

 C_6H_{14}

H₃C CH₂ CH₂ CHCH₃ CH_3

2-methyl pentane

CH₃ H₃C CH₂ CH CH₂CH₃

3-methyl pentane

PREPARATIONS OF ALKANES

Propyne

1. FROM UNSATURATED HYDROCARBONS

Alkanes are prepared by reduction of unsaturated hydrocarbons e.g. alkenes and alkynes.

When an alkene is reacted with H₂, in the presence of a suitable catalyst like nickel at 150°C, platinum (Pt) and paradium (Pd) at room temperature, an alkane is formed.

Alkynes also undergo the same reaction except that excess H₂ is required.

Propane

$$+ 2H_2$$
 $\xrightarrow{Ni}_{150^{\circ}C}$ $+ 2H_2$ $\xrightarrow{Ni}_{150^{\circ}C}$ $+ 2H_2$ $+ 2H_2$

2. FROM HALOGENO ALKANES (ALKYL HALIDES) (R-X)

(i) When alkyl halides are reduced with zinc in the presence of conc. HCl acid, alkanes are formed.

CH₃ CH₂ – C
$$l$$
 + Z n Conc. HC l CH₃ CH₃ + Z n C l ² Chloro ethane

$$Cl$$
 + Zn Conc. HCl + ZnC l_2 Cyclochloro hexane Cyclohexane

$$CH_3$$
 CH_3 CH_3 CH_3 $CH_3 - CH_3 + ZnCl_2$.

 Cl Cl $CH_3 - CH_3 + ZnCl_2$.

2-chlor-2-methyl propane CH_3 CH_3

(ii) When alkyl halides are heated with sodium metal in ether (diethyl ether) alkanes are formed but with increase in carbon chain (doubling the carbon chain). This reaction is known as **Wurtz** reaction and its usually important in organic synthesis when doubling the carbon chain.

2CH₃Br
$$2$$
Na/ether CH₃CH₃ + 2NaBr Bromo methane Ethane

2CH₃CH₂ - C l + 2Na $\frac{ether}{Heat}$ CH₃CH₂CH₂CH₃ + 2NaC l Chloro ethane Butane

2CH₃CH - CH₂ - C
$$l$$
 + 2Na \xrightarrow{ether} CH₃CHCH₂CH₂CHCH₃ + 2NaC l CH₃ CHoro-3-methyl 2-methyl pentane Propane

2CH₃CH CH₂Cl + 2Na
$$\xrightarrow{ether}$$
 CH₃CH CH₂ CH₂ CH CH₃ + 2NaCl CH₃ CH₃ CH₃ CH₃ CH₃ 2, 5-dimethyl hexane.

$$CH_{3}CH_{2} - Cl + CH_{3}C1 \xrightarrow{2Nal\ ether} CH_{3}CH_{2}CH_{3} + 2NaCl$$

$$n - propane$$

$$I + 2Na \xrightarrow{ether} heat + 2NaI$$

$$2 \bigcirc CH_2 - I + 2Na \xrightarrow{ether} \bigcirc CH_2 - CH_2 \bigcirc + 2NaI$$

$$1, 2 \text{ biphenyl ethane.}$$

(iii) Reduction using zinc - copper couple.

Alky halides can be reduced using zinc-copper couple in presence of ethanol to give alkane.

Biphenyl

$$CH_{3}CH_{2}-Cl \xrightarrow{Zn-Cu} CH_{3} CH_{3}$$

$$CH_{2} CH_{2}-Br \xrightarrow{Zn-Cu} CH_{2} CH_{3}$$

$$CH_{2} CH_{2}-Br \xrightarrow{Zn-Cu} CH_{2} CH_{3}$$

$$2 \text{ phenyl ethane.}$$

3. FROM CARBOXYLIC ACIDS AND THEIR SALTS

Alkanes can be prepared from carboxylic acids or salts of carboxylic acids by reacting with fused sodium hydroxide or soda lime.

(i) From carboxylic acids.

Step I:

CH₃CH₂COOH + NaOH
$$\longrightarrow$$
 CH₃ CH₂ CO $_0^-Na^+ + H_2O$
Propanoic acid Sodium propanoate

Step II:

CH₃ CH₂ CO
$$\overline{O}Na^+$$
 + NaOH_(s) \triangle CH₃CH₃ + Na₂CO₃. Ethane

Overall equation:

CH₃CH₂COOH
$$\xrightarrow{Excess\ 2NaOH_{(S)}}$$
 CH₃CH₃ + Na₂CO₃ + H₂O.

Note: This reaction is very important in organic synthesis by reduction of the carbon chain length by one carbon atom.

$$OOONa^{+}$$
 $OOONa^{+}$
 $Heat$
 $Ha_{2}CO_{3} + H_{2}O$

Benzene

CH₃COOH
$$\xrightarrow{Excess\ 2NaOH_{(s)}}$$
 CH₄ + Na₂CO₃ + H₂O Methane

$$\begin{array}{c} & \xrightarrow{CO\overline{O}Na^{+}} & \xrightarrow{Excess\ 2NaOH_{(s)}} & \xrightarrow{H} & +\ Na_{2}CO_{3} \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & &$$

4. FROM CARBONYL COMPOUNDS

Reduction of carbonyl compounds using amalgamated zinc produces alkanes in the presence of conc. HCl.

Carbonyl compounds are aldehydes and ketones containing an oxygen atom in the carbonyl carbon, (C = O) which is removed by zinc and then given to hydrogen to form H_2O . e.g.

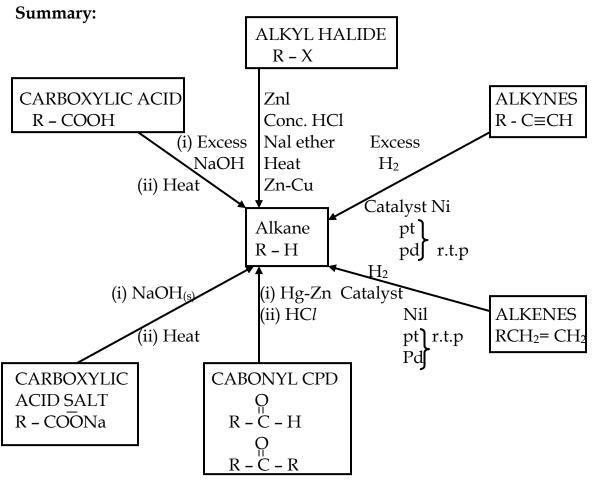

CH₃ - C - H
$$\xrightarrow{Hg-Zn}$$
 CH₃CH₃ + H₂O. (Ethanal aldehyde) Ethane

CH₃ - C - CH₃
$$\xrightarrow{Hg-Zn}$$
 CH₃CH₂CH₃ + H₂O.

$$C - CH_3$$
 $\frac{Hg-Zn}{Conc.HCl}$ $CH_2CH_3 + H_2O$.

5. CRACKING OF HIGHER ALKANES

When higher alkanes are heated under high temperatures, they break down into shorter alkanes and sometimes alkenes are also formed.

Question:

Convert $CH_2 = CH_2$ to CH_4 . $CH_2 = CH_2 + HC1 \longrightarrow CH_3CH_2C1$ ➤ CH₈CH₂OH $H_2O/H+$ $Cr_2O_7^{2-}/H^+(aq)$ Heat Heat CH₃CH₂OH CH₃COOH $\backslash Cr_2O_7^{2-}(aq)$ $Heat \setminus H^+(aq)$ Heat Excess $NaOH_{(s)}$ CH₃COOH $CH_4 + Na_2CO_3$ Heat

36

Complete the following equations, writing the IUPAC name of the main product.

1.
$$CH_3 - CH - COOH \xrightarrow{Excess NaOH_{(s)}} Heat$$

2.
$$CH_3CH_2Cl + 2Na \xrightarrow{ether}$$

3.
$$CH_3$$

$$C = CH_2 + H_2 \xrightarrow{Ni}$$

$$150^{\circ}C$$

4.
$$CH_3CH_2 - Br \xrightarrow{Zn-Hg}$$

Solutions:

1. CH₃ - CH - COOH
$$\xrightarrow{Excess\ NaOH_{(s)}}$$
 \xrightarrow{Heat} $CH_3 + CH_2 + CH_3 + Na_2CO_3 + H_2O$.
CH₃ n - propane

2.
$$CH_3CH_2Cl + 2Na$$
 \xrightarrow{ether} $CH_3CH_2CH_2CH_3 + 2NaCl.$ $n - Butane$

3.
$$CH_3$$

$$C = CH_2 + H_2$$

$$CH_3$$

$$CH - CH_3$$

$$CH - CH_3$$

$$CH - CH_3$$

$$CH - CH_3$$

4.
$$CH_3CH_2 - Br \xrightarrow{Zn-Hg} CH_3CH_3$$
 n – ethane.

PROPERTIES OF ALKANES

PHYSICAL PROPERTIES

(a) **Nature:**

Lower alkanes exist as gases ($C_1 - C_3$) exist as gases at room temperature. This is because they have got low boiling points.

The medium $(C_4 - C_9)$ exist as liquids. Higher alkanes are greater than C_{10} exist as solids at room temperature.

(b) **Boiling and melting points:**

Generally the boiling points and melting points of alkanes are lower than corresponding compounds like alcohols, carboxylic acids.

Explanation:

Alkane molecules are held by weak Vander Waal's forces of attraction while corresponding alcohols and carboxylic acids are held by relatively strong hydrogen bonding.

Within alkanes, the boiling point generally increases with the increase in molecular weight.

Ethane (30) boils at lower temperature than Butane (56).

Explanation:

Increase in the molecular weight increases the size of the molecules which correspondingly increases the Vander Waal's forces of attraction. That is why butane (56) boils at a higher temperature than ethane (30).

However, when branching is considered e.g. pentane.

$$CH_3$$

$$CH_3CH_2CH_2CH_2CH_3 \quad and \quad H_3C - C - CH_3$$

$$CH_3$$

$$CH_3$$

$$mm = 72$$

$$mm = 72$$

$$(n - pentane)$$

$$mm = 72$$

$$(2, 2-dimethyl propane)$$

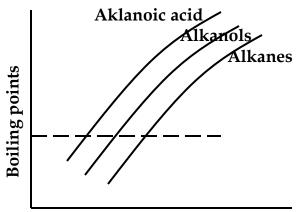

2, 2-dimethyl propane boils at a lower temperature than n-pentane yet both are of the same molecular weight.

38

Explanation:

2, 2-dimethyl propane is highly branched giving it a spherical shape which reduces its size and weaker Vander Waal's forces of attraction will exist between the molecules. While normal pentane is a straight chain molecule which gives the molecule an extended structure resulting into relatively stronger Vander Waal's forces.

A SKETCH SHOWING BOILING POINTS OF ALKANES, ALCOHOL AND CARBOXYLIC ACIDS

Assignment:

The boiling points of alkanes with even and odd number of carbon atoms are not the same.

- (i) Identify how they differ
- (ii) Explain the above difference.

COMBUSTION OF ALKANES

Alkanes usually burn in air to give CO_2 and H_2O only and a lot of heat is produced. This explains why alkanes are used as fuels in domestic and industrial use. E.g. methane is an example of a bio gas that explodes readily to give heat.

Gasoline usually contains propane or butane used in domestic and industrial heating and also to run auto-mobile.

$$CH_4 + 2O_{2(g)} \longrightarrow CO_{2(g)} + 2H_2O_{(l)} + Heat$$

$$C_3H_8 + 5O_{2(g)} \longrightarrow 3CO_{2(g)} + 4H_2O_{(l)} + Heat$$

REACTIONS WITH HALOGENS IN PRESENCE OF (UV) LIGHT OR HEAT

Alkanes are generally unreactive but in the presence of UV radiations (like sunlight), alkanes react with chlorine to form chloro alkane. This is an example of a substitution reaction where H_2 atoms are substituted by chlorine atoms following a free radical mechanism.

A free radical mechanism is a type of reaction where free radicals are involved.

A free radical is a chemical species with unpaired electrons and it is always very unstable but reactive. E.g.

Excess
$$CH_4 + 4Cl_2 \quad \underline{UV} \quad CCl_4 + 4HCl$$

Excess $CH_3CH_3 + Cl_2 \quad \underline{UV} \quad CH_3CCl_3 + 3HCl$

Limited $CH_4 + Cl_2 \quad \underline{UV} \quad CH_3Cl + HCl$

The above reaction is a chain reaction where the products formed become the reactants of the next step.

Therefore, the reaction can then be divided into three;

- (i) Initiation step
- (ii) Propagation step
- (iii) Termination step

INITIATION STEP
$$CL_{2(g)}$$
 UV $2Cl^{\bullet}$

Formation of free radicals using UV. i.e.

$$Cl - Cl$$
 UV 2 Cl^{\bullet} (Free radical)

PROPAGATION STEP

Here the free radicals generated react with neutral molecules to form new radicals.

H -
$$CH_3$$
 + Cl CH_3 + Cl CH_3 + Cl

$$Cl - H + Cl + HCl$$

$$CH_2 + Cl - Gl - CH_2Cl_2 + Cl^{\bullet}$$

H -
$$Cl$$
 + Ch + Ch Cl₂ + HCl

$$CHCl_2$$
 $+$ Cl CH Cl_3 $+$ Cl

$$Cl - Cl - H + Cl - Cl - H + HCl$$

TERMINATION

$${}^{\bullet}CCl_3 + {}^{\bullet}Cl \longrightarrow CCl_4$$

$$Cl^{\bullet} + Cl^{\bullet} \longrightarrow Cl_2$$

$${}^{\bullet}CCl_3 + {}^{\bullet}CCl_3 \longrightarrow Cl_3CCCl_3$$

Note: The above reaction yields a mixture of products and therefore it might be very good in the synthesis of organic compounds. E.g. the above produces a mixture of compounds like chloro methane, Di chloro methane, tri chloro methane, tetra chloro methane.

However, the extent of reaction is determined by the amount of chlorine present.

NITRATION

Alkanes react with HNO_3 acid vapour (heated HNO_3 acid) to form Nitro alkanes, unlike chlorination, in this reaction only one hydrogen atom is substituted by the nitro group.

$$CH_4 + HNO_3$$
 Heat $CH_3NO_2 + H_2O$
Nitro methane $CH_3CH_3 + HNO_3$ Heat $CH_3CH_2NO_2 + H_2O$
Nitro ethane

MECHANISM

$$HO \longrightarrow NO_2$$
 Heat $HO^{\bullet} + {}^{\bullet}NO_2$ Free radicals

$$C - C + H$$

$$H \rightarrow H \rightarrow H_3C + H_2O$$

$$H_3C + NO_2 \rightarrow CH_3NO_2$$

Petroleum industry

- How petrol is formed (distribution of petroleum)
- Cracking of alkanes (thermal cracking)
- Products of a petro chemical industry.
- Uses of alkanes fuels, solvents.

ALKENES

Alkene are unsaturated hydro carbons consisting of a carbon-carbon double bond (- C = C -) as the functional group.

All members in alkene homologous series conform to the general formula C_nH_{2n} .

Propene C_3H_6

NOMENCLATURE

 C_2H_4

Alkenes are named as derivations of alkanes by removing the suffix "ane" and replacing it with "ene". E.g.

$$CH_2 = CH_2$$
 Ethene

$$CH_3 CH = CH_2$$
 Propene

$$CH_3CH CH = CH_2$$
 3 – methyl butene CH_3

$$CH = CH_2$$
 $n - phenyl ethene$

$$CH_3$$
 $H_3C - C = C - CH_3$
 CH_3
 CH_3

 $CH_3CH = CH CH_3 but-2-ene$

 $CH_3CH_2CH_2CH = CH_2$ n – pentene

ISOMERISM

Alkenes exhibit four types of isomerism i.e.

(i) Chain isomerism

Examples: C₄H₈

$$CH_3CH_2CH = CH_2$$
 n – but-1-ene

$$CH_3$$
 $C = CH_2$ 2-methyl prop-l-ene CH_3

(ii) Position isomerism

These differ by the position of the double bond.

E.g. C₅H₁₀.

$$CH_3CH_2CH_2CH = CH_2$$
 pent-l-ene

$$CH_3CH = CH CH_2 CH_3$$
 pent-2-ene

(iii) Ring isomerism

Isomers differ by the shape of the carbon skeleton. Alkene and clycloalkanes are isomeric.

E.g. C₄H8

$$CH_3CH_2CH = CH_2$$
 But ene

$$CH_2 - CH_2$$

 $H_2C - CH_2$ Cyclo butane

$$C_5H_{10}$$

 $CH_3CH_2CH_2CH = CH_2$ Pentene

(iv) Geometrical isomerism

Compounds differ by the different ways in which the atoms are arranged by the double bond. (restricted rotation of a double bond).

Example: But-2-ene.

$$H_3 C$$
 CH_3 C H C CH_3

Cis but-2-ene

$$H_3 C$$
 H $C = C$ CH_3

Tans but-2-ene

Exercise:

Write all the isomers of C₄H₈

1. $CH_3 CH_2 CH = CH_2$

n – but-l-ene

2. $CH_3 - C = CH_2$ CH_3 2-methyl prop-l-ene

3. $CH_3CH = CH CH_3$

but-2-ene

Cyclobutane

5. H_3C H C = C

6. H H C = C CH_3

1 and 2 are chain isomers

3 and 4 are position isomers

5 is a ring isomers

6 is geometrical isomers

METHODS OF PREPARATION OF ALKENES

Alkenes are prepared from a number of ways:

(i) From Alkyl halides (Halogeno alkanes)

When halogeno alkanes are heated with an alcoholic alkaline solution like NaOH or KOH, this reaction is an elimination reaction when both H_2 and the halogen are removed from an alkyl halide to form an alkene as a major product and hydrogen halide as a minor product.

Conditions:

Heat

Alcoholic alkali (NaOH or KOH)

E.g.
$$CH_3CH_2Cl$$
Chloro ethane

$$CH_3CH_2CH_2 Br$$
Bromo propane

$$CH_3CH_2CH_2 Br$$
Bromo propane

$$CH_3CH_2CH_2 Br$$
Bromo propane

$$CH_3CH_2CH_2 Br$$
Fropene

$$CH_3CH_2CH_2 Br$$
Fropene

$$CH_3$$

$$CH_4$$

$$CH_3$$

$$CH_4$$

$$CH_5$$

$$CH_6$$

$$CH_7$$

$$CH_7$$

$$CH_7$$

(ii) Dehydration of alcohols

When alcohol is heated with conc. H₂SO₄ or H₃PO₄ acid in either liquid or vapour phase, an alkene is formed.

Conditions:

Heat at appropriate temperature depending on the type of alcohol (170 – 180°C).

Concentrated acid

E.g. Liquid phase
$$CH_{3}CH_{2}OH \xrightarrow{Conc.H_{2}SO_{4}} CH_{2} = CH_{2} + H_{2}O$$
Ethene

$$CH_{3}CH_{2}OH \xrightarrow{Conc.H_{3}PO_{4}} Heat Cyclo hexanol Cyclo hexanol Cyclo hexanol$$

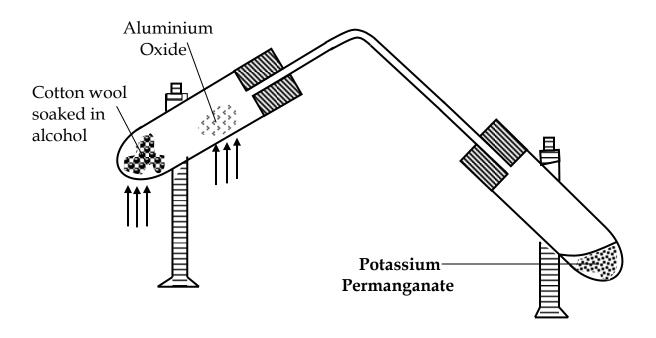

$$CH_{3}CH_{2}OH \xrightarrow{Conc.H_{2}SO_{4}} CH_{3}CH_{2}CH_{2} + H_{2}O$$

$$CH_{3}CH_{3}OH - OH \xrightarrow{Conc.H_{2}SO_{4}} CH_{3}CH_{2}CH_{2} + H_{2}O$$

$$CH_{3}OH - OH \xrightarrow{Conc.H_{2}SO_{4}} CH_{3}CH_{2}CH_{$$

VAPOUR PHASE:

When the vapour of an alcohol generated by heating, the alcohol is passed over heated Al_2O_3 as a catalyst, an alkene is formed.

Observation:

The purple solution of potassium permanganate is decolourised.

E.g.
$$CH_3CH_2OH_{(g)} \qquad \xrightarrow{Al_2O_3} \qquad CH_2 = CH_2 + H_2O.$$

$$\begin{array}{cccc}
OH & & & \\
& \frac{Al_2O_3}{heat} & & & \\
CH_3 & & & & \\
\end{array}$$
+ H₂O

3-methyl cyclo hexanol

3-methyl cyclo hexene.

The above reaction is also known as elimination reaction because an alcohol loses a water molecule and it forms an unsaturated compound.

(iii) Dehydro Halogenations of Vicinal Dihalides

This is a reaction where there is removal of both hydrogen and halogen atoms from one molecule to form unsaturated compound.

A Vicinal dihalide is a compound with two halogen atoms positioned at adjacent carbon atoms. The structure is shown below.

Vicinal is different from a Gem-dihalide.

A Gem-dihalide has got two halogen atoms positioned within the same carbon atom. E.g.

(a) When a vicinal dihalide is heated with zinc in presence of an alcohol, an alkene is formed. E.g.

Cl
$$CH_3 CH = CHCH_3 + Zn \xrightarrow{CH_3CH_2OH} CH_3CH = CHCH_3 + ZnCl_2$$

$$Cl$$

48

2, 3-dichloro butane

$$Cl + Zn \frac{CH_3CH_2OH}{heat} + ZnCl_2.$$

$$CH_{3}CH_{3}CH CH_{3} \xrightarrow{Zn/Ethanol heat} CH_{3}CH = CHCH_{3} + ZnBr_{2}$$

Note: Sodium metal can also be used to give the same products that atoms of sodium are required. E.g.

CH₃CH CH₂ + 2Na
$$\xrightarrow{Ethanol}$$
 CH₃CH = CH₂ + 2NaCl. Cl

(b) Using gem dihalides

Higher alkenes are produced but with an increased number of carbon atoms and this reaction is useful in increasing the carbon length during organic synthesis.

2CH₃CHCHC
$$l_2$$
 + 2Zn Ethanol CH₃CH = CHCH₃ + 2ZnC l_2
2CH₂C l_2 + 4Na Ethanol CH₂ = CH₂ + 4NaCl

(iv) Partial reduction of alkynes

When Alkynes are reacted with hydrogen in equi-molar ratio in presence of a heated catalyst like nickel at 150°C or platinum and palladium at room temperature, an alkene is formed.

$$CH \equiv CH \xrightarrow{Ni/H_2} CH_2 = CH_2$$

$$C \equiv CH$$

$$+ H_2 \xrightarrow{pt} CH = CH_2$$

$$CH_3 - CHC \equiv CH + H_2 \xrightarrow[150^oC]{Ni} CH_3 CH CH = CH_2$$

 CH_3

CHEMICAL REACTIONS OF ALKENES

Alkenes are generally very reactive compared to alkanes. This is so because alkenes have a double bond consisting of π electrons which can be easily donated to reactants (electrophiles).

A double bond in alkenes is also shorter and stronger; that means its releases high energy compared to a single bond.

Bond	Energy KJ mol ⁻¹	Length (mm)
C - C	346	0.154
C = C	598	0.134

The above make alkenes reactive to electrophiles.

TYPES OF REACTIONS

(a) Addition reactions

Alkenes undergo addition reactions where a double bond is converted to a single bond.

(i) Hydrogenation (Reduction)

Alkenes react with H₂ in presence of heated catalyst of Nickel at 150°C or platinum and palladium of at room temperature to form alkanes. In this reaction all the hydrogen atoms are added across a double bond.

$$CH_2 = CH_2 + H_2 \xrightarrow{Ni} CH_3CH_3$$

$$CH_3 = CH_2 + H_2 \xrightarrow{150^{o}C} CH_3CH_3$$

$$Cyclo hexene Cyclo hexane$$

$$CH_3 CH_2 CH = CH_2 + H_2$$

$$Pt$$

$$CH_3 CH_2 CH_2 CH_3$$

$$+ 2H_2$$

$$\frac{Ni}{150}$$

This reaction forms the basis of synthesizing saturated compounds from unsaturated e.g. formation of margarine when unsaturated fats are heated with H_2 in presence of a catalyst to form a fat (margarine).

Determination of stability of compounds like Cis and trans-forms of alkenes, benzene and cyclo – 1, 3, 6 – triene.

CH₃ C = C CH₃ + H_{2(g)}
$$\xrightarrow{Ni}$$
 CH₃CH₂CH₂CH₃ + heat(28.6KJ)
H H

$$H$$
 $CH_3 C = CCH_3 + H_{2(g)} \xrightarrow{Ni} CH_3CH_2CH_2CH_3 + heat(27.6KJ)$

The Cis form is unstable compared to the trans form.

$$+ 3H_{2(g)} \longrightarrow + heat$$

Mechanism:

$$CH_2 = CH_2 + H^{\delta-} - H^{\delta-} Pt \longrightarrow CH_3 + +_{CH_2} +: H^- Pt$$
Carbon cation ion

(ii) Halogenation

Alkenes react with halogens like Cl_2 , Br_2 , I_2 in presence of an organic solvent like carbon tetra-chloride to form a dihalide compound.

$$CH_3 + I_2 \underline{CCl_4} \qquad I$$

1, 2-di iodo -2-methyl cyclo hexane.

$$CH = CH_2 + Br_2 + CCl_4$$
 $CHCH_2Br$
 Br
 $1, 2 \text{ dibromo-2-phenyl ethane.}$

Mechanism:

$$CH_{3}CH = CH_{2} \longrightarrow CH_{3}+CHCH_{2}Cl + :Cl^{-}$$

$$Cl^{\delta+} - Cl^{\delta-}$$

$$CH_{3}+CHCH_{2}Cl \longrightarrow CH_{3}CH CH_{2}Cl$$

$$:Cl^{-} \longrightarrow CH_{3}$$

$$CH_{3} \longrightarrow CH_{3}$$

$$CH_{3} \longrightarrow CH_{3}$$

$$CH_{3} \longrightarrow CH_{3}$$

$$I^{\delta+} \longrightarrow I^{\delta-} \longrightarrow CH_{3}$$

$$I \longrightarrow CH_{3}$$

If the same reaction is done in the presence of H₂O, then the product formed is an hydroxyl halogeno alkane. This is because the OH generated from water is a better nucleophile than the halogen in addition to its presence in excess.

$$CH_2 = CH_2$$
 H_2O/Br_2 $HOCH_2$ CH_2 Br 2-bromo ethanol

Mechanism

$$CH_2 = CH_2 Br^{\delta +} - Br^{\delta -} - CH_2CH_2Br + :Br^{-}$$

$$+CH_2 - CH_2 Br - CH_2CH_2Br - H + HOCH_2CH_2Br + H^{+}$$

$$+CH_2 - CH_2 Br - H + HOCH_2CH_2Br + H^{+}$$

$$H^+ + Br^- \longrightarrow HBr.$$

$$CH_3$$
 Cl_2/H_2O CH_3 + HCl OH Cl

Mechanism:

$$CH_3$$
 $Cl^{\delta+} - Cl^{\delta-}$
 $CH_3 + :Cl^{-}$

$$CH_3$$
 CH_3
 $O^+ - H$
 Cl
 CH_3
 CH_3
 $O^+ - H$
 Cl
 CH_3
 OH
 Cl

 $H^+ + Cl^- \longrightarrow HCl.$

 $CH_3CH = CH_3$ Br_2/H_2O $CH_3CH - CH_2 + HBr.$

Mechanism:

CH₃CH
$$=$$
 CH₂ \longrightarrow CH₃+CH CH₂ Br + Br⁻

$$Br^{\delta+} - Br^{\delta-}$$

$$CH_3^+CH CH_2 Br \longrightarrow CH_3 CH CH_2 Br \xrightarrow{-H^+} CH_3 CHCH_2 Br + H^+$$
 $:OH_2$
 $:O$

Alternatively: $H_2O + Br_2 \longrightarrow HOBr + HBr$ $CH_3 CH = CH_2 \longrightarrow CH_3^+CHCH_2 Br + :\bar{O}H$ $Br \longrightarrow OH$ $CH_3^+CHCH_2Br \longrightarrow CH_3CHCH_2Br$

Reactions with halogen acids (HX)

Alkenes react with halogen acids to form alkyl halides. This reaction is an addition reaction that can proceed into two ways according to the conditions of reaction.

(i) Electrophillic addition

This reaction occurs readily in the absence of a peroxide following an ionic mechanism.

(ii) Free radical mechanism

This occurs in the presence of a peroxide. In both types of reaction, the products formed are different.

$$CH_2 = CH_2 + HBr$$
 — CH_3CH_2Br .

Bromo ethane.

$$CH_3CH = CH_2 + HBr \xrightarrow{peroxide} CH_3CH_2CH_2Br.$$
1-bromo propane (free radical mechanism)

MARKWONIKOFF RULE

Markwonikoff rule predicts the products formed when halogen acid is reacted with unsymmetrical alkene.

The rule states that addition of an halogen acid to unsymmetrical alkene gives a product where the hydrogen is added to the carbon atom with the lower number of hydrogens and the halogen atom is added to the hydrogen atom across a double bond to a carbon atom with few H₂ atoms.

This reaction is followed in the absence of a peroxide. E.g. CH₃OOCH₃ (peroxide) or ROOR.

In the presence of a peroxide, anti Makwonikoff's rule applied where the hydrogen from the halogen acid is added to the carbon atom across the double bond with the highest hydrogen atom and the halogen goes to the carbon atom with the least hydrogens.

Examples:

1.
$$CH_3 + HBr \longrightarrow CH_3$$
 Br
 H

2.
$$CH_3C = CHCH_3 + HCl \longrightarrow CH_3 C CH_2 CH_3$$

$$CH_3 \qquad CH_3$$

3.
$$CH_3 CH = CH_2 + HBr \xrightarrow{ROOR} CH_3 CH_2 CH_2 Br$$

4.
$$CH_3$$
 CH_3 $CH_3 - C = CH_2 + HCl$ ROOR $CH_3 - CH_3 + CH_$

MECHANISM (MARKWONIKOFF RULE)

CH₃ C = CH CH₃ + HC
$$l$$
 \longrightarrow CH₃ C - CH₂ CH₃
CH₃

$$CH_3$$
 $C = CH$ CH_3 $H - Cl$ $slow$ $CH_3 - C - CH_2CH_3 + :Cl$ CH_3

$$Cl$$

$$CH_3 + C CH_2 CH_3 \longrightarrow CH_3 C - CH_2 CH_3$$

$$CH_3 CH_3$$

$$CH_3$$
 CH_3 CH_3

MECHANISM (ANTI MARKWONIKOFF)

$$CH_3$$
 CH_3 CH_3

$$CH_3$$
 CH_3 CH_2Cl + $CH_3CH CH_2Cl$ + Cl

The reactions follow a more stable carbo cation ions in the order of $3^{\circ} > 2^{\circ} > 1^{\circ}$.

REACTIONS OF ALKENES WITH H₂O IN PRESENCE OF AN ACID(H₂O/H⁺(aq)

MINERAL ACID WATER

When an alkene is heated with H_2O in presence of H_2SO_4 acid, an alcohol is formed. This reaction is known as hydration of alkenes and is used in the preparation of alcohols.

Example:

1.
$$CH_3CH = CH_2 \xrightarrow{H_2O/H^+} CH_3 CH CH_3$$
OH
Propane Propan-2-ol

2.
$$\underbrace{\frac{H_2SO_4/H_2O}{heat}}_{Cyclo \ hexene} OH$$
Cyclo hexene

3.
$$CH_3$$
 CH_3 CH_3

4.
$$\frac{H_2O/H^+}{heat}$$
 CH₃ OH

2-methyl cyclo hexene methyl cyclo hexan-1-ol

Mechanism:

$$H^{\delta-} - Q^{\delta-}SO_3H \longrightarrow H^{+} + \bar{O}SO_3H$$

$$H^{+} + \bar{O}SO_3H \longrightarrow H_2SO_4.$$

NOTE: If the reaction is done by first reacting the alkene with the sulphuric acid, the intermediate formed is (Alkyl hydrogen sulphate).

OSO₃H
$$\frac{H_2O}{Heat}$$
 OH + H_2 SO₄.

On diluting and warming, the product formed is the alcohol.

CH₃ CH = CH₂
$$\xrightarrow{H_2O/H^+(aq)}$$
 CH₃ CH CH₃ OH

Propan-2-ol

Mechanism:

$$CH_3 CH = CH_2 \bullet H^+ \longrightarrow CH_3 + CH CH_3$$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \xrightarrow{-H^+} CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH CH_3 \longrightarrow CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3 CH CH_3$
 $CH_3 + CH_3 CH CH_3 \longrightarrow CH_3$
 $CH_3 + CH_3 CH_3$

REACTIONS WITH MOLECULAR O₂.

Alkenes react with molecular O_2 in presence of a heated silver catalyst to form Expoxides. Hydrolysis of expoxides with water produced d-ols.

CH₃ CH = CH₂ + O₂
$$\xrightarrow{2AG}$$
 CH₃ CH - CH₂ + Ag₂O O

Propane expoxide

CH₃ CH - CH₃
$$H_2O$$
 CH₃ CH CH₂ OH OH Propanes 1, 2-diol.

This reaction can also occur, when alkenes are reacted with peroxo acids. E.g. Benzene peroxo acid.

CH₃ CH = CH₂ + C₆H₅ C - O - OH
$$\longrightarrow$$
 CH₃ CH - CH₃ + O Expoxides

O

C₆H₅ - C - OH

Benzoic acid

REACTIONS WITH OZONE (O₃)

Alkenes react with ozone to form ozonides hydrolysis of ozonides in the presence of;

NaPab
$$\underline{H_2O}$$
 Na⁺ + Pab⁻

Zinc and H₂O produces carbonyl compounds.

$$CH_3 CH = CH_2 + O_3$$
 $CH_3 CH$
 CH_2
 $O-O$

Propane ozonide

CH₃ CH CH₂
$$\xrightarrow{Zn/H_2O}$$
 CH₃ CH + HC H + ZnO

Ethanol Methanal

The above reaction is very important in two main ways.

- (i) In organic synthesis of converting an alkene to a carbonyl compounds of aldehyde and ketone.
- (ii) It is important in the analysis of the structure of the original alkene. If one product is formed after the hydrolysis of the ozonide, then the alkene used is asymmetrical where the double bond is at the centre. But if two products are formed, then the alkene is unsymmetrical.

HCHO + CH₃ CHO
$$\leftarrow \frac{ZnO}{H_2O}$$
 CH₃ CH - O - CH₂

OXIDATION REACTION OF ALKENES

Alkenes undergo oxidation reaction using mild oxidizing agents like Alkaline potassium permanganate to form di-ols.

During this reaction, observation made is that the purple solution mixture, turns colourless (purple solution decolourised).

This test indicates the presence of a double bond which is converted to a saturated compound.

$$CH_2 = CH_2 \xrightarrow{\bar{O}H(aq)/Mn\bar{O}_4} + HO - CH_2 CH_2 OH$$

Ethene Ethane-1, 2-diol

CH₃ CH = CH₂
$$\xrightarrow{KMnO_4/\bar{O}H}$$
 CH₃ CH CH₂ OH
OH
Propane -1, 2- diol

MECHANISM:

$$KMnO_4$$
 \longrightarrow $K^+_{(aq)} Mn\bar{O}_4(aq)$

$$CH_3 CH = CH_2 \longrightarrow CH_3 - CH - CH_2$$

$$O O : O Mn$$

$$O O O O$$

Inequilibrium

$$CH_3$$
 $CH - CH_2 \longrightarrow CH_3 - CH - CH_2 OH + MnO_4^{2-}$
 $OH \longrightarrow OH$
 $OH \longrightarrow OH$
 $OH \longrightarrow OH$

POLYMERISATION

Alkenes undergo polymerisation known as addition polymerisation due to the presence of a double bond, enabling the monomer units to repeatedly combine to form high molecular mass products known as polymers.

During polyermerisation, a catalyst is required in order to initiate the formation of free radicals.

Catalysts popularly used include;

- (i) Molecular oxygen/peroxide
- (ii) Metallic catalyst.

Example:

1. n CH₂ = CH₂
$$\frac{O_2 \ Catalyst}{Heat \ (high \ temp.)}$$
 $+$ $(CH_2 - CH_2)$ n

Ethene Polythene (Polymer) (Monomer)

2.
$$n \text{ CH}_3 \text{ C} = \text{CH}_3 \xrightarrow{O_2 \text{ catalyst} \atop \text{High temp.} \atop \text{High pressre}}$$
 Cl Cl Cl Cl

3.
$$C_1 CH = CH$$
 $High temp.$
 $High pressure$
 $CH - CH_2$
 Cl
 Cl

4.
$$n \longrightarrow \frac{CH = CH_2}{\frac{Peroxide}{Heat, high \ pressure}} \longrightarrow \frac{C}{n} - CH_2$$

Styrene

Polystyrene

5.
$$n ext{ CH}_3 ext{ CH} = ext{CH} - ext{CH} = ext{CH}_2 ext{ CH}_3 ext{ CH}_3 ext{ CH}_3 ext{ Rubber}$$

6.
$$CH_3$$
 $CH_3 C = CH - CH_3$
 $\frac{catalyst}{heat,pressure}$
 $CH_3 C + CH_3$
 $CH_3 CH_3 CH_3$

7.
$$CH_3$$
 $CH_2 = C - CH = CH_2$
 CH_3
 CH

Mechanism:

$$\overrightarrow{RO}$$
 $CH_2 = \overrightarrow{CH_2}$ $RO - CH_2 - {^{\bullet}CH_2}$

RO CH₂ CH₂
$$\longrightarrow$$
 RO CH₂CH₂CH₂CH₂

Termination:

 $RO CH_2 CH_2 --- CH_2 CH_2 --- CH_2 CH_2 OR.$

ALKYNES

Alkynes are unsaturated hydro carbons which contain a triple bond in the carbon skeleton as their functional group.

They have a general formula C_nH2_{n-2} where $n \ge 2$.

NOMENCLATURE AND ISOMERISM OF ALKYNES

The name of alkyne is formed by replacing the end n, from the corresponding "ane" with "yne" as shown below.

Alkyne IUPAC name:

 $HC \equiv CH$ Ethyne $CH_3C \equiv CH$ Propyne $CH_3C \equiv C CH$ Butyne

$$C \equiv CH$$
 Phenyl ethyne.

$$HC \equiv CC \equiv CH$$
 Buta-1, 3- diyne.

Alkynes show chain, functional and position isomerism.

PREPARATION OF ALKYNES

- (a) Only ethyne can be prepared by the following methods:
 - (i) Partial combustion of methane, yields ethyne.

$$2CH_4 + O_2 \longrightarrow HC \equiv CH + _4H_2O.$$

(ii) Heating of methane in absence of air at 1500°C also yields ethyne. CH₄ 1500°C C₂H₂

64

(iii) Hydrolysis of calcium carbide also yields ethyne. $CaC_2 + H_2O \longrightarrow Ca(OH)_2 + C_2H_2$.

GENERAL METHODS FOR PREPARATION OF ALKYNES

DIHALOGENATION OF DIHALOGENATED ALKENES

This is done by using alcoholic KOH. It is an elimination reaction in which two moles of halogen acids (HX) are lost e.g.

CH₃CH₂ CH CH₂
$$\xrightarrow{KOH/Alcohol}$$
 CH₃ C \equiv CH + KC l + H₂O.

Mechanism:

KOH
$$\longrightarrow$$
 K+ + ŌH.

$$CH_3 CH_2OH + \bar{O}H \longrightarrow CH_3CH_2 \bar{O} + H_2O.$$

CH3 C-CH₃ CH₃ C = CH
$$\longrightarrow$$
 CH₃ C = CH
 Cl \downarrow O CH₂CH₃ \downarrow O CH₂CH₃

TYPES OF ALKYNES

Alkynes are classified according to the position of the triple bond.

- (i) Terminal
- (ii) Symmetrical
- (iii) Unsymmetrical

Examples:

$$CH_3C \equiv CH$$
 Terminal/unsymmetrical $CH_3CH_2C \equiv CH$ Butyne

 $CH_3C \equiv CCH_3$ Symmetrical but not terminal buta-2-yne.

 $CH_3C \equiv CCH_2CH_3$ Unsymmetrical but non terminal penta-2-yne.

 $CH_3C \equiv CCH_2C \equiv CCH_3$ Hepta-2, 5-diyne.

 $CH_3 \equiv CC \equiv CH \text{ buta-1, 3-diyne.}$

PREPARATION OF ALKYNES

FROM DIHALOGENO ALKANES

When dihalogeno alkanes are heated with excess alkali in the presence of an organic solvent like ethanol, dehydrohalogenation occurs giving an alkyne.

Convert
$$CH_2CH_2OH \longrightarrow C \equiv CH$$

Phenyl ethynol

Phenyl ethyne

CH₂CH₂OH
$$\frac{Conc.H_2SO_4}{180^{\circ}C}$$
CH = CH₂

$$Cl_2/CCl_4$$

$$Cl CH = CH_2$$

$$Cl Cl CH = CH_2$$

$$Cl CH = CH_2$$

Mechanism:

$$Cl$$
 CH_3 - CH - CH_2Cl
 $Excess \ alcholic$
 $NaOH/Heat$
 $CH_3C \equiv CH$

NaOH + EtOH
$$\rightleftharpoons$$
 EtŌNa+ + H₂O
EtŌNa+ \longrightarrow EtŌ: + Na+.

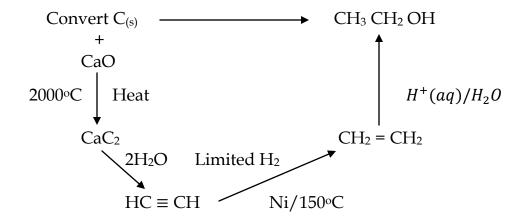

CH₃ C₁ CH₂ Cl
$$\rightarrow$$
 CH₃ C \equiv CH₃

(ii) From CaO.

This method is specifically for ethyne.

$$CaO_{(s)} + 3C_{(s)}$$
 \xrightarrow{Heat} $CaC_2 + CO_{(g)}$

$$CaC_{2(s)} + 2H_2O_{(s)} \longrightarrow HC \equiv CH + Ca(OH)_2$$

(iii) From alkane (CH \equiv CH)

Partial oxidation of alkanes.

$$CH_4 + \frac{1}{2}O_2 \longrightarrow HC \equiv CH + H_2O$$

$$2CH_4 \longrightarrow CH \equiv CH + 3H_2$$

Thermal cracking

REACTIONS OF ALKYNES

(i) Electrophilic addition

Is where an electron seeking species is added across a triple bond. Alkynes are very reactive because of the presence of π electrons in a triple bond. This reaction is essentially like that of alkenes, however, 2moles of the electrophile are required to saturate an alkyne.

(ii) Addition of halogen (
$$X_2$$
)
 $CH \equiv CH + Cl_2 \quad CCl_4$ $ClCH = CHCl_2$ Cl_2/CCl_2

Mechanism:

$$CH \equiv CH \quad Cl \quad Cl \quad H \quad C = +CH + :Cl^{-}$$

$$Cl$$

$$H C = CH \longrightarrow H - C = CH$$

$$Cl$$

$$Cl$$

$$Cl$$

(iii) Halogen acids (HX)

Alkynes react with halolgen acids to give dihalides depending on the structure of an alkyne, the dihalide can either be a gem or vicinal due to Makwonikoff's rule.

$$CH \equiv CH + 2Br \longrightarrow CH_3CHBr_2$$

$$Cl \qquad CH_3C \equiv CH + 2HCl \longrightarrow CH_3 C CH_3$$

$$Cl \qquad CH_3$$

$$Cl \qquad CH_3$$

$$CH_3C \equiv CH + 2HBr$$
 $ROOR$ $CH_3 CH_2 CH Br.$

$$C \equiv CH + 2HBr$$

$$C \equiv CH + 2HBr$$

$$C CH_{5}$$

$$Br$$

(iv) With H₂O.

Alkynes react with H₂O in the presence of H₂SO₄ acid and HgSO₄ with a temperature of about 60°C to form carbonyl compounds. A symmetrical alkyne forms a ketone.

$$CH_3C \equiv CCH_3 + H_2O \xrightarrow{H_2SO_4/HgSO_4} O$$

$$CH_3 C CH_2 CH_3$$

$$Butan-2-one$$

$$CH_3C \equiv CH + H_2O$$
 $\xrightarrow{H_2SO_4/HgSO_4}$ CH_3CH_2CHO Propanal

(v) Reactions with H_2 .

Alkynes just like alkenes react with H_2 when passed over a suitable catalyst like Ni/150°C, pt/r.t.p to form an alkane.

$$CH \equiv CH + 2H_2 \xrightarrow{Ni} CH_3CH_3$$

$$CH_3C \equiv CH + 2H_2 \xrightarrow{pt} CH_3CH_2CH_2$$

(vi) Nitrile formation

When little NH₃ is passed over an alkyne heater over an Al catalyst at 573°C, a nitrile is formed.

CH
$$\equiv$$
 CH + NH₃ $\xrightarrow{Al_{(s)}}$ CH₃ CN + H₂
Ethanonitrile

(vii) Polymerisation

Due to the presence of a triple bond, alkynes polymerise to form cyclic or aromatic compounds. This occurs when an alkyne is heated in a glass tube containing Fe catalyst (4000°C).

$$3CH \equiv CH \frac{Fe}{4000^{o}C}$$

When two molecules of ethyne combine by passing them through a saturated solution of copper(I) chloride in ammonium chloride, vinyl ethyne is formed.

Vinyl ethyne is a good starting material for linear polymers.

$$2CH \equiv CH \frac{cucl}{NH_4cl}$$
 $CH_2 = CHC \equiv CH$ Vinyl ethyne.

$$CH_2$$
 = CHC \equiv CH + CH \equiv CH CH_2 = CH CH = CHC \equiv CH

A terminal proton of an alkyne can be substituted by other electropositive metals. This indicates that, such alkynes are acidic.

NOTE: Only terminal alkynes behave this way. Non terminal do not.

CH CH + 2Na Liquid NH₃
$$\uparrow_N^+ a\overline{C} \equiv \overline{C} \text{Na}^+ + \text{H}_2.$$

$$2CH_3C \equiv CH + 2Na$$
 Liquid NH_3 $2CH_3C \equiv \bar{C} Na^+ + H_2$.

WITH AMMONIACAL COPPER(I) CHLORIDE SOLUTION

Similary, H₂ in alkynes can be substituted when its passed in solution of CuC₁ NH₃ giving a red precipitate of Cu⁺ alkyne derivative. This reagent is called ammoniacal copper(I) chloride solution, CuCl/NH_{3(aq)}.

$$HC \equiv CH + CuCl \xrightarrow{NH_{3(aq)}} CuC \equiv CCu + 2HCl.$$
Red ppt.
Copper(I) ethyne (or Copper acetylide)

WITH AMMONIACAL SILVER NITRATE SOLUTION.

When a terminal alkyne is bubbled through a solution of ammonial AgNO₃, a white precipitate of silver dicarbide is formed.

$$HC \equiv CH + 2 \text{ AgNO}_3 + 2NH_{3(aq)}$$
 \longrightarrow Ag $C \equiv C \text{ Ag}_{(s)}$ White ppt + $2NH_4NO_3$.

Differentiate between CH_3 $C \equiv CH$ and CH_3 $C \equiv CCH_3$

Reagent: Ammoniacal copper(I) chloride solution. With $CH_3C \equiv CH$: No observable change.

With $CH_3C \equiv CCH_3$: A red precipitate is observed.

The above reactions are used for distinguishing between terminal alkynes and non terminal

SYNTHESIS OF HIGHER ALKYNES

When an alkyne is passed through liquid NH₃ in presence of Na metal and the derivative formed is reacted with an alkyl halide, the chain is increased giving a higher alkyne.

HC
$$\equiv$$
 CH + 2Na Liquid NH₃ $^{+}_{N}a\bar{C} \equiv \bar{C}$ Na⁺ + 2CH₃Cl
CH₃C \equiv C CH₃ + 2NaCl
CH₃C CH + Na NaNH₂ CH₃C $\equiv \bar{C}$ Na⁺

Physical properties of alkynes

 $CH_3C \equiv \bar{C}Na^+ + CH_3CH_2Cl$

- They are insoluble in H₂O.
- They are very soluble in organic solvents like benzene, CCl₄.
- They are less dense than H_2O .
- Their boiling points increase in number of carbon atoms. E.g. Ethyne boils at -75, propane -43, butyne at 91.

 $CH_3 C \equiv CCH_2 CH_2 + NaCl$

- They have got almost the same boiling points as those of corresponding alkenes.
- They have got the same vanderwaal's forces of attraction.

Convert
$$CH \equiv CH$$
 CH_3 CH_3 CH_3 CH_3 CH_4 CH_5 CH_5 CH_5 CH_5 CH_6 CH_6 CH_6 CH_7 CH_8 CH_8

AROMATIC COMPOUNDS (ARENES)

The term aromatic is derived from the Greek work Aroma to mean sweet smell. This term has been carried forward by modern Chemists used as aromatic to mean or describe the study of compounds with benzene ring.

Benzene is a parent compound of aromatic compounds.

STRUCTURE AND BONDING OF BENZENE

Structure and bonding of benzene was made clear by analysis made by Chemists. They found out that a clear colourless compound was isolated from distillation of crude oil and on analysis, it was found to contain 92.3% carbon and 7.7% hydrogen only.

When 0.250g of this liquid was vapourized at 100°C, they found out that the liquid occupies 98cm³. The results were subjected to analysis.

Element Percentage composition	C 92.3	H 7.7	
Relative atoms	92.3	7.7	
Moles	7.69	7.70	
Mole ratio	7.69 7.69	7.70 7.69	
	1	1	
Empirical formula =	СН		
Volume of gas at 100(373)K			

$$= \frac{\cancel{24 \times 373}}{\cancel{293}}$$

$$= 30.04 \text{ dm}^3$$

98cm³ of liquid contain 0.25g at 100°C.

Mass of 1mol
$$\left(\frac{6.25 \times 30040}{98}\right) g$$

= $76.6 \stackrel{\frown}{=} 77g$.

(CH)_n = 77

$$12n + n = 77$$

$$n = \frac{77}{13}$$

$$n = 5.0 = 6.$$

Molecular formula is C₆H₆.

The structure proposed was C₆H₆ with all its isomers.

In 1865, Kekule proposed that the structure of benzene molecule is not a straight chain but an hexagonal ring consisting of alternating double bonds.

But a number of evidences proved out that the above structure, proposed by Kekule was not true. Benzene does not have true double bonds since it does not undergo addition reaction with bromine in darkness.

EVIDENCE PUT TO EXPLAIN BENZENE STRUCTURE.

(i) X-ray structure determination to measure the length of carbon-carbon bonds.

Compound	Bond	Length/nm
Cyclo hexane	C - C	0.154
Cyclo hexene	C = C	0.134
Benzene	CC	0.140

The measurements of the bond length showed that, the bond length of benzene are between single and double, therefore are not true double bonds ruling out Kekule's structure of double bonds.

(ii) Thermodynamic measurements:

(a) Enthalpy of hydrogenation.

Cyclo hex-1, 3, Cyclo hexane
$$\Delta H = 3(119)$$
Cyclo hex-1, 3, Cyclo hexane -357 KJ mol⁻¹.

+
$$3H_2$$
 $\Delta H = -207 \text{ KJ mol}^{-1}$.

Benzene

Conclusion:

The double bonds of benzene are not true double bonds. Benzene is more stable than cyclo hex-1, 3, 5, triene by an extra 150 KJmol⁻¹

(b) Enthalpy of formation of benzene.

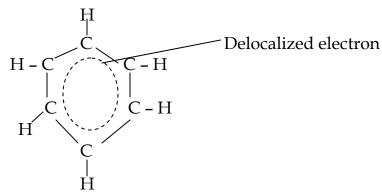

The theoretical/calculated enthalpy of formation of benzene is 252 KJ mol⁻¹ but the practical value of this energy is 82 KJ mol⁻¹. This means benzene is more stable by 170 KJ mol⁻¹ of energy.

$$6C_{(s)} + 3H_{2(g)} \longrightarrow C_6H_{6(g)} \Delta H = 82 \text{ KJ mol}^{-1}.$$

(c) Reactions of benzene

Benzene does not undergo addition reactions but undergoes substitution reactions implying it does not have double bonds but a system of delocalized electrons or the pie (π system).

DELOCALIZATION OF BENZENE STRUCTURE

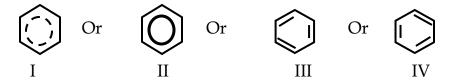

Benzene structure has got six δ carbon – carbon bonds.

It has got $3-\pi$ carbon – carbon bonds.

The π bonds are not localized but they are shared by the six carbon atoms giving a π system of electrons and this is called delocalization.

STRUCTURE OF BENZENE.

BENZENE

Is the parent aromatic compound with a hexagonal ring of carbon atoms having a π system of electrons.

FORMATION OF BENZENE

(i) From dehydrogenation of cyclo hexane when heated with Pt/Pd or heated with sulphur. Cyclo hexane loses H₂ atoms to form benzene.

$$\frac{Pt/Pd}{heat} \longrightarrow + 3H_2$$

$$\frac{S}{heat} \longrightarrow + 3H_2S$$

(ii) Polymerisation of ethyne

When ethyne is heated with an organo iron or Nickel, it undergoes cyclisation to form benzene.

$$3CH \equiv CH \qquad \frac{Fe}{heat} \qquad \bigcirc$$

$$3CH \equiv CH \qquad \frac{organo-Ni}{heat} \qquad \bigcirc$$

(iii) Decaboxylation of benzoic acid

When benzoic acid is heated with soda lime (a mixture of (NaOH and CaO).

(iv) From benzene diazonium SaH.

When benzene diazonium salt is reacted with pypophosphorus acid in presence of water, benzene is formed.

The formation of benzene diazonium alt can be started from phenyl amine which is reacted with a mixture of $NaNO_2$ and HCl (HNO₂ acid) at a temperature <10.

$$NH_2$$

$$\xrightarrow{NaNO_2/Conc.HCl}$$
 $<10^{\circ}C$
 \sim

Benzene diazonium salt.

$$NH_{2} \xrightarrow{NaNO_{2}/Conc.HCl} \xrightarrow{NaNO_{2}/Conc.HCl} \xrightarrow{N^{+} \equiv NCl^{-}}$$
 Benzene diazonimu chloride salt.
$$H_{2}O \xrightarrow{Benzene} H_{3}PO_{2} \qquad C_{6}H_{5}N_{2}Cl$$
 Benzene.

(v) Catalytic reformation of petroleum under heat of about 550° C in the presence of Cr_2O_3/Al_2O_3 .

CH₃(CH₂)₄ CH₃
$$\xrightarrow{cr_2o_3}$$
 $\xrightarrow{550^oC}$ + 4H₂
Hexane Benzene

(vi) From phenol

When phenol is heated with zinc dust, benzene is formed.

PROPERTIES OF BENZENE

PHYSICAL PROPERTIES

- ✓ It is a colourless liquid.
- ✓ It has got a x-tic smell.
- ✓ It is insoluble in water but dissolves in organic solvents e.g. CCl₄, methyl benzene.
- ✓ It burns with a highly sooty flame.

CHEMICAL PROPERTIES

Benzene undergoes electrophillic substitution reaction where the hydrogen atom on the ring is replaced by another electrophille. Benzene therefore reacts mainly with electrophilles (Positively charged species) to form substituted products on the benzene ring.

(i) Nitration reaction

Is a reaction where the nitronium ion ${}^{+}NO_{2}$, O = +N = O) substitutes the hydrogen in the benzene ring. The electrophille of the nitronium ion is generated from a mixture of Conc. $H_{2}SO_{4}$ and Conc. HNO_{3} acid heated at a temp. of $60^{\circ}C$.

$$\frac{Conc.H_2SO_4/Conc.HNO_3}{heat/60^{\circ}C} + H^{+}$$
Nitro benzene

Mechanism:

$$H_2SO_4 + NO - NO_2$$
 Protonation $H_2O^+ = NO_2 + HSO_4^-$

$$H_2O^+ \longrightarrow H_2O + {}^+_NO_2$$

$$O = {}^{+}_{N} = O$$

$$H$$

$$NO_{2}$$

$$NO_{2}$$

$$NO_{2}$$

$$NO_{2}$$

$$NO_{2}$$

$$H$$

$$H$$

(ii) Sulphonation:

This is a reaction where benzene reacts with Conc. Or fuming H_2SO_4 acid to form benzene sulphuric acid.

The electrophille in this reaction is SO₃ which is a neutral electrophille generated from fuming sulphuric acid.

$$2H_2SO_4$$
 $SO_3 + H_3O^+ + HSO_4^-$

$$O = S - O^{-}$$

$$O = S - O^{-$$

(iii) Halogenations

Benzene reacts with halogens like Cl_2 , Br_2 only in the presence of halogen carrier which polarizes the halogen molecule by accepting the lone pair of electrons so that the eletrophille is generated.

In the absence of the halogen carrier, benzene does not react with halogens.

Examples of halogen carries used are:

$$\bigcirc$$
 + Br₂ Fe Br₃ Br + HBr

$$\frac{3I_2/Fe}{Heat} + HI$$

Mechanism:

$$+ Cl_2 \xrightarrow{Fe_{(s)}} Cl$$

$$3Cl_{2(s)} + 2Fe_{(s)}$$
 heat $2FeCl_3$

$$Cl^{\delta+}$$
 $-Cl^{\delta-}$ $FeCl_3$ $[FeCl_4]^-Cl^+$

$$Cl^{+}[FeCl_{4}]^{-} \longrightarrow H^{+} FeCl_{4}^{-}$$

$$FeCl_4^- + H^+ \longrightarrow FeCl_3 + HCl$$

Alkylation of Benzene

This is the reaction where an aromatic compound reacts with an alkyl halide in the presence of a halogen carrier to form an alkyl aromatic compound.

This reaction was first identified by **Friedel craft**. It is also called Friedel Craft alkylation.

$$CH_3$$
 - CH_3 - CH_3

$$H^+ + FeBr_4^- \longrightarrow Fe Br_3 + HBr.$$

$$+ CH_2 = CH_2$$
 $+ CH_2 = CH_3$.

Benzene reacts with alkenes in presence of a mineral acid. The mineral acid is necessary to form an elctrophille.

$$+ CH_3 CH = CH_2 \xrightarrow{H_2 Po_4(aq)} CH_3 \qquad H_3C - CH - CH_3$$

$$CH \qquad Or \qquad CH_3$$

$$CH \qquad Or \qquad CH_3$$

$$CH_{3}CH = CH_{2} + H^{+} \longrightarrow CH_{3} + CH CH_{3}$$

$$+ CH_{3}CH = CH_{3} + HCl \xrightarrow{AlCl_{3}}$$

$$+ CH_{3}CH = CH_{3} + HCl \xrightarrow{AlCl_{3}}$$

Acylation

Is a reaction of benzene with acid halides in the presence of halogen carriers to form aromatic ketones at a temperature of 50°C.

1.
$$CH_3COCl$$
 Ethanol/ Chloride Phenyl ethanone

2. CH_3 + CI_3 + CI_4 + $CI_$

$$Al Cl_4^- + H^+ \longrightarrow Al Cl_3 + HCl.$$

Hydrogenation:

Benzene react with hydrogen in presence of Ni catalyst when heated at 150°C to form cyclo hexane.

$$+$$
 H_2 \xrightarrow{Ni} $150^{o}C$

Halogen in presence of light (uv).

When chlorine is mixed with benzene in the presence of sun light or uv rays, the benzene ring becomes highly substituted with chlorine atoms to form 1, 2, 3, 4, 5, 6 hexa chloro benzene.

Combustion

Benzene burns in air with a sooty flame to form CO₂ and H₂O.

$$+ \frac{1}{2}O_{2(g)} \longrightarrow 6CO_{2(g)} + 3H_2O_{(l)}.$$

DERIVATIVES OF BENZENE

Derivatives of benzene react differently depending on the behaviour of the group of atom(s). the chemical behaviour of these groups are divided into three groups.

- (i) The group which substitutes the benzene ring directing any incoming group 2(ortho) and 4(para) position directors. E.g.
 - (a) OH-group, ethoxide group OCH₃, CH₃-gp, NH₂-nitro group, amides O gp-HN- C CH₃.

These groups have got positive inductive effect by pushing the electrons towards the ring, activating the benzene ring so that the electrons are available at positions 2, 4, and 6 where the incoming electrophille are added.

By activating the ring, they increase the electron density on the ring so that the electrophilles are added faster.

Usually two products are given, i.e. position 2 and position 4 products.

METHYL BENZENE

1.
$$CH_3$$

$$\frac{HNO_3/Conc.H_2SO_4}{(Faster) < 60^{\circ}C}$$

$$\frac{2 \text{ nitromethyl}}{2 \text{ nitromethyl}}$$

$$OC$$

Alkylation of methyl benzene.

$$CH_3$$
 + CH_3Cl $Al Cl_3$ + CH_3 + CH_3 + CH_3 + CH_3

(a) Halogation of methyl benzene.

$$CH_3$$
 + Cl_2 $Al Cl_3$ + Cl_3 + Cl_3 + Cl_3

(b) Halogenation of methyl benzene in presence of sunlight (UV).

This reaction follows a free radical mechanism.

CHLORO BENZENE

Chloro benzene or other halogeno benzene compounds can substitute the ring at position 2 and 4 but at a much slower rate. This is because halogens have got a negative inductive effect (electronegative) and withdrawal electrons from the ring towards themselves so that the pie electrons on the ring can be availed to electropilles at position 2 or 4 where there is a high electron density.

$$\begin{array}{c}
Cl \\
+ \frac{Conc.H_2SO_4/Conc.HNO_3}{heat} \\
+ CH_3Cl \\
\end{array}$$

$$\begin{array}{c}

NO_2
\end{array}$$

$$\begin{array}{c}
Cl \\
NO_2
\end{array}$$

$$\begin{array}{c}
Cl \\
CH_3
\end{array}$$

Groups that direct further substitution at position 3 of the ring do so at a much slower rate including COOH, NO₂, CN, SO₃H.

BENZOIC ACID

COOH Meta(3) position directors.

Carboxylic acid on benzoic acid directs the incoming substituents at position 3 so that one major product is formed.

(i) COOH
$$\frac{Conc.HNO_3/Conc.H_2SO_4}{Heat}$$
NO2
3-nitro benzoic acid.

(ii) COOH
$$CH_3Cl$$
 COOH CH_3

(iii) Sulphonating

COOH

fuming
$$H_2SO_4$$

SO₃H

(iv) NO_2
 $Conc.HNO_3/Conc.H_2SO_4$

Heat

The above are Meta (3) directors because they pull electrons away from the ring and decreasing electron density at position 2 or 4 and the only place where the electrons are available is the Meta position.

DISTRIBUTED COMPOUNDS

When there are two substituents on the benzene ring, the orientation effect of these two will be determined or predicted by their reinforcing effects or the order of their superiority. The following order is normally observed.

- OR > NR₂ > Alkyl group > halogen > Meta directors.

CH₃

$$NO_2$$

$$SO_3H$$

$$NO_2$$

$$SO_3H$$

$$Cl \atop Cl \atop Cl \atop HSO_3 Cl +$$

ALKYL HALIDES

(Halogeno alkanes)

Alkyl halides are compounds in which halogen atoms are directly attached onto the hydro carbon chain or aromatic ring.

R – X where R = Alkyl or Aryl group.

$$X = \text{Halogen atom } (Cl, Br, I, F)$$

When the halogen is attached to the aromatic ring, it is called aromatic halide. e.g.

$$\bigcirc$$
 Cl \bigcirc Br.

When the halogen is directly attached to the hydro carbon, it is called alkyl halide / halogen alkane. E.g.

CH₃CH₂Cl, CH₃Br, CH₃CHCH₃

Chloro ethane Bromo methane İ 2-Iodo propane.

ALKYL OR HALOGENO ALKANES

Nomenclature:

Alkyl halides are named as derivatives of corresponding alkanes y inserting the number and the prefix, chloro, Bromo, Iodi, Fluoro, to the alkane name.

Example:

CH₃ CH CHCH₃ 2-chloro-3-methyl butane.

$$CH_3$$
 $CH_3 - C - Br$
 CH_3
 CH_3
 CH_3
 CH_3

ISOMERISM

Alkyl halides exhibit two types of isomerism.

- (i) Chain isomerism
- (ii) Positional isomerism

CHAIN ISOMERISM:

These arise as a result of difference in the arrangement of carbon atoms giving different carbon skeleton but the position of the halogen atom remains the same. $C_4 H_9 Br$.

- 1. CH₃ CH₂ CH₂ CH₂ Br 1-Bromo butane.
- 2. CH₃ CH CH₂ Br 1-Boromo-2-methyl propane. CH₃

POSITIONAL ISOMERISM:

These arise as a result of the different positions taken by the halogen atom on the same chain. E.g.

C₄ H₉ Br.

CH₃ CH₂ CH₂ CH₂ Br 1-Bromo butane

CH₃ CH₂ CH CH₃ 2-Brobom butane Br

METHODS OF PREPARATION:

Alkyl halides are prepared from the following:

(i) From Alkenes:

Addition of an halogen acid to an alkene at room temperature gives an alkyl halide. When unsymmetrical alkene is used, addition of an halogen acid gives a product predicted by Makwonikoff's rule. But if a peroxide used, then the product will be that of anti Makwonikoff's rule.

1.
$$CH_3CH = CH_2 + HBr$$

$$r.t.p$$

$$CH_3 CH CH_3$$

2.
$$CH_3 CH = CH_2 + HBr \xrightarrow{ROOR} CH_3 CH_2 CH_2 Br.$$

3.
$$CH = CH_2$$
 + HCl CH CH_2

5.
$$CH_3$$
 $C = CH_2 + HCl$ Cl_3 Cl_3 Cl_3 Cl_3

Mechanism:

$$CH_3$$

$$C = CH_2$$

$$H^{\delta +} Cl^{\delta -} slow$$

$$+C - CH_3 + Cl^{\delta -} CH_3$$

$$CH_3$$
 $+C - CH_3$
 CH_3
 $C - CH_3$
 $C - CH_3$
 C
 C
 C

(ii) From Alkanes

When alkanes are reacted with a halogen molecule in presence of UV rays of sunlight. A mixture of alkyl halides are formed but if the reaction conditions are controlled by using excess alkane or limited halogen molecule, then the product formed would be one type of alkyl halide.

Excess:

$$CH_3 CH_2 CH_3 + Cl_2$$
 $U.V$ $Sunlight$ $CH_3 CH_2 CH_2 Cl + HCl.$

$$CH_3 + Cl_2$$
 UV $CH_2Cl + HCl.$

(iii) From Alcohols:

Alcohols are the most important source of preparing alkly halides in reaction where hydroxyl groups of alcohol are replaced by halogen atoms which could be derived from: - halogen acids (HX).

- Phosphorus tri or penta halides (PX₃/PX₅)
- Thiony chloride (SOC*l*₂).

(a) Action of halogen acid on the alcohol:

When a halogen acid is heated with an alcohol in presence of a dehydrating agent e.g. - Zn Cl₂ (anhydrous)

- Conc. H₂SO₄.

- Al_2O_3 (Dry)

An alkyl halide is formed. Sometime the halogen acid is generated "insitu."

$$R - OH + HX \longrightarrow R - X + H_2O.$$

$$CH_3 CH_2 OH$$
 $NaCl/Conc.H_2SO_4$ $CH_3CH_2 - Cl + H_2O.$

$$CH_{3} - C - OH \xrightarrow{Conc.HCl} CH_{3} - C - Cl + H_{2}O$$

$$CH_{3} - C - Cl + H_{2}O$$

$$CH_{3} - C - Cl + H_{3}O$$

A solution of anhydrous $ZnCl_2$ in Conc.HCl (Lucas reagent) is an important reagent for distinguishing the three classes of alcohols i.e.

- Primary.
- Secondary and tertiary alcohols.

The tertiary alcohol gives an immediate cloudy solution of an alkyl halide. (0.5 minutes).

The secondary alcohol gives cloudy solution between 5 and 10 minutes.

The primary alcohol does not give a cloudy solution at room temperature.

(b) Action of phosphorous halides:

When alcohols are refluxed with phosphorous halide like phosphorous tri chloride or phosphorous penta chloride, the halogeno alkanes or alkyl halides are formed.

$$R - OH + PCl_5 \xrightarrow{refluxed} R - Cl + POCl_3 + HCl.$$

$$CH_2OH$$
 $Refluxed$ $CH_2Cl + POCl_3 + HCl.$

$$3CH_3 CH_2 OH + PCl_3 \xrightarrow{reflux} 3CH_3 CH_2 Cl + H_3PO_3.$$

(c) Action of thionyl chloride (SOCl₂):

When alcohols are refluxed in presence of thionyl chloride in the presence of an organic base pyridine to neutralize the mixture of toxic gases, an alklyl halide is formed.

This is a very convenient way of preparing alkyl halides.

$$CH_3CH_2OH + SOCl_2 \xrightarrow{pyridine} CH_3 CH_2 Cl + SO_2 + HCl$$

$$CH_2 OH + SO Cl_2$$
 pyridine $CH_2 Cl + SO_2 + HCl$.

REACTIONS OF ALKYL HALIDES

CLASSES OF HALOGENO ALKANES

(i) Primary Alkyl halides RCH₂ CH₂ - X.

Here the halogen atom is attached to a carbon is which bonded to only one another.

(ii) Secondary alkly halide. R - CH - R²

Here the halogen atom is attached to a carbon atom which is bonded to two other carbon atoms.

(iii) Tertiary alkly halide:

$$\begin{array}{c}
 R^1 \\
 R^2 - C - X \\
 R^3
 \end{array}$$

Here the halogen atom is attached to a carbon atom which is bonded to three other carbon atoms.

The three classes of alkly halides given above react differently due to the stability of the carbo cation ion which is formed as an intermediate during the reaction. The stability is governed by the order that tertiary > secondary > primary.

PHYSICAL PROPERTIES:

Lower alkyl halides are gases at room temperature.

The medium ones are liquids and the higher ones are solids.

The boiling points of alkyl halides with the same number of carbon atoms is determined by the atomic size of the halogen which later is as a result of the Van de Waal's forces of attraction.

95

$$I^- > Br^- > Cl^- > F^-$$
.

CHEMICAL PROPERTIES:

Halogen atoms being more electronegative than carbon means that the C – X bond is highly polar due to the presence of partial induced charge where the halogen is partially negative and carbon is partially positive.

The polarity of the C – X bond makes alkyl halides to be very reactive to the nucleoptile thus necleophillic substitution.

$$\begin{array}{c|c}
 & \downarrow \\
 & -C \\
 & \downarrow \\
 & Nu
\end{array}$$

$$\begin{array}{c|c}
 & -C \\
 & -X \\
 & Nu
\end{array}$$

$$\begin{array}{c|c}
 & Nu \\
 & Nu
\end{array}$$

The type of halogen present also determines the reaction.

The electronegativity difference between the halogen together with the bond length determines overall the reactivity. Down the group of the halogens there is decrease in electronegativity and at the same time increase in the bond length.

The reaction becomes faster with Iodo-alkanes than Bromo chloro fluoro alkanes because of low electronegativity in the iodides.

NUCLEOPHILLIC SUBSTITUTION REACTIONS

(i) Reaction with alkalis:

Alkalis react with alkly halides to form alcohols when they are refluxed.

$$CH_3Cl + {}^-_0H_{(aq)} \quad \xrightarrow{\text{Reflux}} \quad CH_3OH + \mathcal{C}l^-(aq)$$

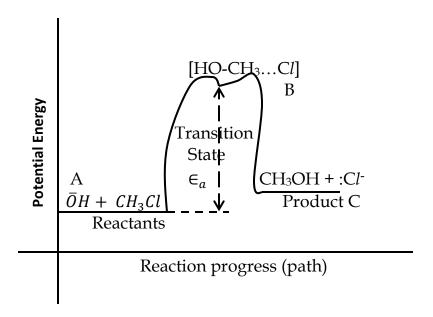

$$\begin{array}{ccc} CH_3 & CH_3 \\ H_3C - \overset{\overline{o}H_{(aq)}}{C} - Br & & \overset{\overline{o}H_{(aq)}}{heat} & H_3C - \overset{\overline{o}H_{(aq)}}{C} - OH + Br_{(aq)} \\ CH_3 & CH_3 & CH_3 \end{array}$$

$$CH_2Br$$
 $\xrightarrow{KOH_{(aq)}}$ $CH_2OH + KBr.$

Primary alkyl halides with aqueous alkali.

Primary alkyl halides follow nucleophillic substitution bimolecular (SN_2) mechanism. Is a type of reaction where two molecules involve the rate determining step.

$$CH_3^{\delta+} - Cl^{\delta-} \underline{slow} \qquad [HO \dots CH_3 \dots Cl] \xrightarrow{fast} HO - CH_3 + : Cl^{-}$$

The nucleophille which is $\bar{O}H$ approaches the carbon atom carrying halogen from the opposite side.

This partially forms a nucleophille carbon bond and at the same time, a carbon halogen bond partly breaks. This leads to the increase in potential energy from A to B.

At B, there is partial halogen bond broken and partial nucleophille bond formed. This state is known as **activation complex** or **transition state**.

The energy level between the reactants and the activation complex is called the **activation energy**.

Later, the potential energy of the system increases when all the carbon halogen bonds are broken and the carbon nucleophille bonds are formed.

The energy of the system finally decreases until point C where the product of the alcohol is finally formed. This type of reaction is categorized as SN₂ reactions mechanism because there are two molecules involved at the activated complex.

Mechanism:

$$H\bar{0}$$
:

 OH
 $CH_3 - CH^{\delta +} - CH_3 \longrightarrow CH_3 - CH - CH_3 + :Cl^ Cl^{\delta -}$
 $:Cl^- + Na^+_{(aq)} \longrightarrow NaCl.$

The mechanism followed by secondary alkyl halides is always between SN_1 and SN_2 .

(iii) Tertiary alkyl halides

$$CH_3$$
 CH_3 CH_3

Tertiary alkyl halides follow SN₁ mechanism. Here only the alkyl halide molecule is involved in the activated complex and thus its concentration alone determines the order of reaction.

Mechanism:

$$CH_3$$
 CH_3 $H\bar{0}$:

 C^+ Fast $HO-C-CH_3$
 CH_3 CH_3

REACTIONS WITH ALKA OXIDES (Na, K)

Alkyl halides react with sodium or potassium alka oxides to form ethers under heat.

$$CH_3CH_2Cl + CH_3\overline{O}Na^+ \xrightarrow{heat} CH_3CH_2OCH_3 + NaCl.$$
 Ethoxy methane.

Mechanism:

CH₃CH₂
$$\overline{0}$$
N_a⁺ slow CH₃CH₂ $\overline{0}$ (aq) + Na⁺

CH₃CH₂O: CH₂ δ + $\int Br^{\delta}$

CH₂OCH₂CH₃ + Br

Na⁺(aq) + Br⁻(aq) NaBr.

REACTIONS WITH SILVER SALTS OF CARBOXYLIC ACIDS

Alkyl halides react with silver salts of carboxylic acids when refluxed to form esters. This reaction uses the alkanoate ion as the nucleophille.

CH₃ CO
$$\overline{0}$$
Ag⁺ + CH₃CH₂ Cl Reflux CH₃ C OCH₂ CH₃ + AgCl Ethyl Ethanoate

 CH_3
 CH_3
 CH_3
 CH_3
 CH_3
 CH_3

$$Ag^{+}_{(aq)} + Cl^{-}_{(aq)} \longrightarrow AgCl_{(s)}.$$

REACTIONS WITH POTASSIUM CYANIDE (KCN)

Alkyl halides react with KCN in presence of an alcohol when refluxed to form alkyl nitriles.

Condition (reflux) – alcohol present.

Nucleophile $\overline{C} \equiv N$ or $\overline{C}N$.

Example:

$$CH_3CH_2Cl + KCN \xrightarrow{heat} CH_3CH_2CH_2CN + KCl$$
Propy nitrile.

$$KCN \longrightarrow K^+ + \bar{C}N.$$

$$N\overline{C}$$
:
 $CH_2^{\delta+} \longrightarrow CH_2 - CN+: Br^{-1}$

$$K^+_{(aq)} + Br^-_{(aq)} \longrightarrow KBr.$$

Note:

- (i) The above reaction is important inorganic synthesis, more especially increasing the carbon length (chain) by a single carbon.
- (ii) Silver cyanide can also be used instead of potassium cyanide.

Convert CH₃COOH to CH₃CH₂COOH.

REACTIONS WITH SILVER NITRITE (AGNO₂).

Alky halides react with AgNO₂ when refluxed to form a mixture of nitro alkanes and alkyl nitrite. Such types of reactions are not important in synthesis since they yield a mixture of products.

$$CH_3 Cl + AgNO_2$$

$$\frac{heat}{reflux}$$
 $CH_3 O - N = O Methyl nitrite.$

$$AgNO_2 \longrightarrow Ag^+ + N\overline{O}_2.$$

$$O = N - \overline{0};$$

$$CH_3^{\delta +} - Cl^{\delta -} \longrightarrow CH_3O - N = O + Cl^{-}$$

$$Methyl nitrite$$

$$Ag^+ + Cl^- \longrightarrow Ag Cl^-(aq)$$

Or:
$$O = \dot{N} - \overline{O}$$
: $CH_3^{\delta+} - Cl^{\delta-} \longrightarrow CH_3NO_2 = 0 + Cl^-$ Nitro methane

$$Ag^+ + Cl^- \longrightarrow AgCl.$$

REACTIONS WITH AMMONIA AND AMINES

Alkyl halides react with conc. NH₃ to form a mixture of amines when heated in a sealed tube. A mixture of amines are produced because a product at one stage become a nucleophille for the next stage. The nucleophille is ammonia and the amines.

ELIMINATION REACTIONS OF ALKYL HALIDES

(Quaternary amine)

These are reactions that will result into the formation of unsaturated compound with elimination of a water molecule. Alkyl halides when refluxed or heated with an alkali (KOH, NaOH) in the presence of an alcohol, they from alkene. The reaction can also be effected by using a strong base which is an alka oxide.

Strong base (Alka oxide)

$$CH_2Br$$
 $\frac{2Na}{dry\ ether}$ $CH_2 - CH_2$ + 2NaBr.

DIHALIDES COMPOUNDS

There are compounds that have got two halogen atoms within the same carbon chain.

There are two types of dihalides;

(i) Vicinal dihalide

This contains two halogen atoms located on any adjacent carbon atom i.e. H_2C – CH_2

Example:

CH₂ Cl CH₂ Cl

1, 2-dichloro ethane.

2, 3-dibromo butane.

1, 2-dichlorophenyl ethane.

(ii) Gem dihalides

These contain the two halogen atoms located on the same carbon atoms.

i.e.

Example:

2, 2 dichloro propane

CH₃ CH Cl₂

1, 1-dichloro ethane.

PREPARATION OF DIHALIDES

Dihalides are prepared from the following reactions:

(i) From Alkenes

When alkenes are reacted with halogens in presence of CCl₄ (organic base) at room temperature, a vicinal dihalide is formed.

$$CH_2 = CH_2 + Cl_2$$
 $\xrightarrow{CCl_4}$ $Cl CH_2 CH_2 Cl.$

(ii) From alkynes and halogen acids

When alkynes react with halogen acids (excess), a gem dihalide is formed.

$$CH_3 C \equiv CH + 2HBr \xrightarrow{heat} CH_3 C - CH_3$$
Br

$$HC \equiv CH + 2HCl \xrightarrow{ROOR heat} H_3C - CCl_2.$$

(iii) From carbonyl compounds (Aldehydes and Ketones).

When a carbonyl compound is reacted with phosphorous pental tri chloride, a dihalide is formed. Usng aldehydes, will produce a gem dihalide and ketones also produce gem dihalide.

PHYSICAL PROPERTIES OF AROMATICS

They are colourless liquids or solids with characteristic flame.

They are insoluble in H_2O but soluble in organic solvents like $CC l_4$.

NOTE:

They do not easily undergo necleophillic substitution unlike alkyl halide.

Distinguish between OCl and CH₂CH₂Cl

Reagent: Hot aqueous NaOH in dil HNO3 and AgNO3.

Observations: - A white precipitate forms with CH₂Cl.

- No observable change with Cl.

ALCOHOLS AND PHENOLS:

These are compounds that contain hydroxyl group. Therefore the functional group is hydroxyl group. The difference between alcohol or alkanols and phenol is that the hydroxyl group is directly attached to the aromatic ring in phenols.

Alkanol Phenol R - OH Ar - OH

ALKANOLS OR ALCOHOLS

Alcohols are organic compounds derived from hydro carbons but where one or more hydrogens is/are replaced by hydroxyl group. The general formula is R – OH where R is an alkyl group or simply represented as CnH_2n+1 OH. Where n = simple number.

They are also called alkanols simply because a hydroxyl group replaces a hydrogen.

TYPES OF ALCOHOLS

There are basically three types of alcohols:

- (i) Monohydric alcohol

 This is one that has got one hydroxyl group.
- (ii) Dihydric alcohol

 This is one that has got two hydroxyl groups.
- (iii) Polyhydric alcohol These have got more than two hydroxyl groups e.g. $HO CH_2 CH CH_2 OH$ OH

NOMENCLATURE

Alcohols are named as alkanols according to the IUPAC. This is done by replacing the last "e" in alkane name with suffix "ol" (functional group name).

The position of the functional group has to be indicated just before the suffix "ol.

If the stem name has got a vowel, then a consonant letter must be added just before the position of the functional group.

E.g. CH₃ CH₂ OH Ethano-1-ol

CH₃CH CH₃ Propan-2-ol OH

CH₃
CH₃
CH₃
CH₂ CH₃
2-methyl butan-2-ol.
OH

 $HO - CH_2CH_2OH$ Ethane-1, 2 – diol

HO - CH₂CH (OH) CH₂ OH Propane - 1, 2, 3 - triol.

OH Cyclohexan-1-ol

 CH_3 CH_3 C - OH CH_3 CH_3 2-methyl propan-2-ol CH_3

Cyclohexan-1, 3-diol Xyclohexane-1, 3-diol

Phenyl methan-1-ol.

NOTE:

Loot at isomerism in alcohols.

Types – structural:

- (i) Chain
- (ii) Position
 - Functional (alcohol and others are isomeric).

CLASSES OF ALCOHOLS

Monohydric alcohols are classified into three classes.

(i) Primary alcohol

This has one alkyl group attached to the carbon atom carrying the -OH group. E.g. \cdot C - OH H

(ii) Secondary alcohol

This has got two alkyl groups attached to the carbon atom carrying the OH group.

(iii) Tertiary alcohol

This has three alkyl groups attached to the carbon atom carrying the OH group.

METHODS OF PREPARATION

(i) From alkyl halide (SN reaction)

When alkyl halides are refluxed with aqueous alkali IKOH or NaOH) or with moist silver oxide, alcohols are formed.

This is a hydrolysis reaction that occurs by nucleophillic substitution reaction.

$$CH_3 CH_2 Cl + NaOH_{(aq)} \xrightarrow{warm} CH_3 CH_2 OH + NaCl$$

$$CH_3 - C - CH_3 + \bar{O}H_{(aq)} \xrightarrow{heat} CH_3 - C - CH_3 + I^-$$

$$CH_3 - C - CH_3 + \bar{O}H_{(aq)} \xrightarrow{heat} CH_3 - C - CH_3 + I^-$$

$$Br + KOH_{(aq)} \xrightarrow{heat} OH + KBr.$$

$$Cl$$
 OH $CH_3 CH CH_3 + AgOH_{(aq)}$ CH $_3 CH CH_3 + AgCl$.

(ii) From alkenes

When alkenes are reacted with dilute mineral acid water and heated, an alcohol is formed. They usually used acid is H₂SO₄ acid.

If the mixture is not heated, then an alkyl hydrogen sulphate is formed.

CH₂ = CH CH₃
$$\xrightarrow{H^+/H_2O}$$
 H - CH₂ CH₂ - CH₃

CH₂ = CH CH₃ $\xrightarrow{H_2SO_4/H_2O}$ CH₃CH₂ CH₃
HSO₄

Mechanism:

$$H^{\delta+} - O^{\delta-}SO_3H$$

CH₃ CH
$$\neq$$
 CH₂ $\stackrel{}{}$ CH₃ - +CH CH₃.
CH₃ +CH CH₃ $\stackrel{}{}$ CH₃ - CH - CH₃ $\stackrel{}{}$ -H⁺ CH₃ CH CH₃ + H⁺ OH OH $\stackrel{}{}$ OH $\stackrel{}{}$ OH $\stackrel{}{}$ OH $\stackrel{}{}$ OH $\stackrel{}{}$ CH₃ CH CH₃ + $\stackrel{}{}$ OF $\stackrel{}{}$ CH₃ CH CH₃ + $\stackrel{}{}$ OSO₃H $\stackrel{}{}$ CH₃ +CH CH₃ $\stackrel{}{}$ OSO₃H $\stackrel{}{}$ OSO₃H $\stackrel{}{}$ OSO₃H $\stackrel{}{}$ OSO₃H

NOTE:

H₂O acts as a nucleophile that will react with the alkyl hydrogen sulphate in the last step to form an alcohol. i.e.

$$CH_3$$
 CH CH_3 CH

When alkenes are reacted with H_2O in presence of Al_2O_3 , an alcohol is formed. E.g.

$$CH_3CH = CH_2 + H_2O \xrightarrow{Al_2O_3} OH$$
 $CH_3 CH CH_3$

$$+ H_2O \xrightarrow{Al_2O_3} OH$$

(iii) From carbonyl compounds (Aldehydes and ketones)

Carbonyl compounds are reduced in the presence of a suitable reducing agent to alcohols.

Aldehydes [H] Primary alcohols

Ketones [H] Secondary alcohols

Reducing agents normally used:

Hydrogen in presence of catalyst, Ni/150, Pt/pd, r.t.p.

Using Li Al H₄ (Lithium, Aluminium, Tetra hydride) in presence of dry ether.

Sodium boron tetrahydride (NaBH₄)

CH₃ CH₂ CH + H₂
$$\xrightarrow{Ni}$$
 H₃ CH₂ CH₂OH
Propanal Propanol

(iv) **Hydrolysis of esters**

Esters are hydrolyzed in presence of mineral acids or alkalis to form corresponding alcohols and carboxylic acids. This reaction is not very useful for synthesizing alcohols because of the mixture of alcohol and acid.

CH₃ C OO CH₂ CH₃
$$\frac{H^+(aq)}{heat}$$
 CH₃ COOH + CH₃ CH₂ OH

CH₃ O C CH₃ $\frac{OH_{(aq)}}{heat}$ CH₃ OH + CH₃ COOH

Ethyl ethanoate

Mechanism: (look for acid/base hydrolysis of esters).

(v) From primary amines

CH₃ NH

They react with HNO₂ acid which is generated "insitu" by reacting sodium nitrite and conc. HCl to form alcohols. This reaction is only for primary amines and not secondary or tertiary.

CH₃ NH
$$\frac{Na No_2/HCl}{heat}$$
 CH₃OH + N₂ + H₂O

CH₂ NH₂ $\frac{Na No_2/HCl}{heat}$ CH₂ OH + N₂ + H₂O.

From fermentation of carbohydrates. (vi)

PROPERTIES OF ALCOHOLS

PHYSICAL PROPERTIES

Lower members are liquids, higher members are solids at r.t.p with x-tic smell.

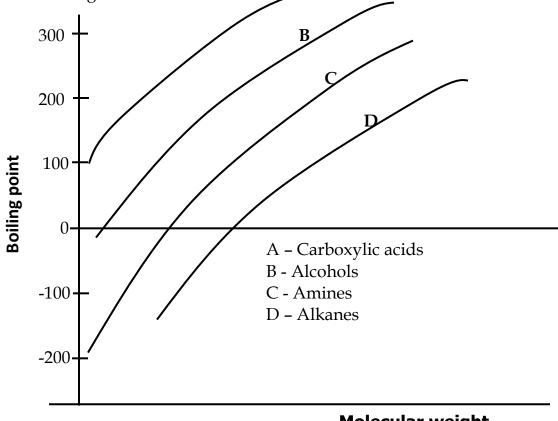

The lower members are very soluble in H₂O but the solubility decreases with the molecular mass.

Alcohols have got relatively higher boiling points compared to similar hydro carbons of approximately the same molecular mass.

Examples:

	Molecular weight	Boiling points
Ethane	30	-42
Methanol	32	46
Butane	58	-0.5
Propan-ol	60	98

Graph showing the variation of boiling points (°C) of different compounds with molecular weight.

Molecular weight

Note:

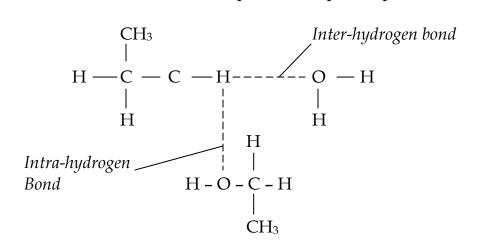

The boiling points increase generally with increase in molecular weight. Increase in molecular weight increases the Van Der Waal's forces of attraction. This makes the compound stronger hence high boiling points.

Explanation:

The boiling points of the compounds above on the graph are determined by hydrogen boding.

Carboxylic acids have got the highest boiling points due to extensive hydrogen bonds which makes molecules to dimerise in a liquid hence difficult to separate them during boiling so that they escape to vapour.

Alcohols' boiling point is higher than that of alkanes but lower than that of carboxylic acid because of inter and intramolecular hydrogen bonding. Molecules will interact in liquids and aqueous phases and high boiling point.

Amines boil at a lower temperature than alcohols of the corresponding molecular weight because nitrogen is less electronegative than oxygen so the hydrogen bonds formed in amines are weaker than in alcohols thus amines boil at a lower temperature.

Alkanes have the least boiling point because of the absence of hydrogen with only Van der Waal's forces of attraction which are weaker and easily broken during boiling.

In summary:

The solubility in water and the boiling points of alcohols are due to hydrogen bonding.

Questions:

- 1. Methyl amine (mm = 31) boils at -6.3°C while methanol (mm = 32) boils at 46°C. Explain.
- 2. 2-methyl propan-2-ol boils at a lower temperature than butan-1-ol yet they all have the same molecular weight.

2 methyl propan-2-ol is highly branched giving it a spherical shape which decreases on the size and weakens the Van der Waal's forces of attraction existing between the molecules.

Butan-1-ol is a straight chain molecule which gives it an extended structure resulting in relatively stronger Van der Waal's forces.

CHEMICAL PROPERTIES OF ALCOHOLS

Alcohols consists of three major bonds that are involved in a chemical reaction.

- (i) Functional group OH group. Where the O – H bond is involved in the reaction.
- (ii) Oxygen-carbon bond which is highly polarized.
- (iii) Alkyl groups R group.

REACTION INVOLVING CLEAVAGE OF THE O - H BOND

Reactions with electropositive metals:

When an alcohol is reacted with a metal like sodium or potassium, an alka oxide and H_2 gas are formed.

$$2R - OH + 2Na_{(s)}$$
 \longrightarrow $2R - \overline{O}Na^{+} + H_{2}$
 $CH_{3} CH_{2} OH + Na_{(s)}$ $\xrightarrow{r.t.p}$ $2CH_{3}CH_{2}\overline{O}Na^{+} + H_{2(g)}$
 $CH_{2} - OH + 2K_{(s)}$ \longrightarrow $CH_{2}\overline{O}Ka^{+} + H_{2(g)}$

Observation:

Effervescence of a colourless gas that burns with a pop sound.

Reactions with mineral acids:

When an alcohol is reacted with a mineral acid, a salt is formed.

$$R - OH + HCl \longrightarrow R - {}_{0}^{+}H_{2}Cl$$

$$CH_{3} CH_{2} OH + HCl \longrightarrow CH_{3} CH_{2} {}_{0}^{+}H_{2}Cl$$

From the two reactions above, alcohols are regarded as amphoteric because they react with acids and bases to show both acidic and basic.

Esterification

Alcohols react with carboxylic acids in presence of mineral acids to form esters. This reaction is known as esterification.

CH₃ CH₂ OH + CH₃ CH₂ COOH
$$\frac{H^+}{heat}$$
 CH₃CH₂ COCH₂CH₃ + H₂O Ethyl propanoate

COOH + CH₃ CH₂ OH
$$\frac{H^+}{heat}$$
 O COCH₂ CH₃ + H₂O Ethyl benzoate.

Mechanism:

$$\begin{array}{c}
O : \\
C - O - H
\end{array}$$

$$\begin{array}{c}
O^{+}H \\
O - O - H
\end{array}$$

$$O^+H$$
 C^-OH
 C^-OH
 CH_3CH_2OH

$$O H$$

$$O H$$

$$O C$$

$$O_{+} - CH_{2} CH_{3} \longrightarrow C$$

$$CH_{3}CH_{2} - O - H$$

Alcohols react with acid chlorides to form esters.

$$O$$
 $CH_3CH_2OH + CH_3 C Cl \longrightarrow CH C OCH_2 CH_3 + HCl$
Ethanol
Chloride

$$CH_3OH + HCOCl \longrightarrow HCOCH_3 + HCl$$

$$OH + CH_3 \overset{O}{C}Cl \implies O \\ COCH_3 \\ Cyclohexayl ethanoate.$$

Mechanism:

$$C - Cl^{\delta -} \longrightarrow H - C - O_{+} - CH_{3} \longrightarrow HC - O_{+} - CH_{3}$$

$$CH_{3}OH$$

$$CH_{3}OH$$

$$CH_{3}OH$$

$$O H \\
H C - O - CH_{3}$$

Alcohols react with acid anhydrides to form esters.

Alkylation of alcohols

Alcohols react with dialkyl sulphates to form ethers and alky derivatives. This reaction involves replacement of hydrogen in the alcohol with alkyl group.

$$R - OH + R_2SO_4 \longrightarrow R - O - R + RHSO_4$$

REACTIONS INVOLVING CLEAVAGE OF A CARBON OXYGEN BOND

In these reactions, we are removing both oxygen and hydrogen atoms from the alcohol.

Reactions with halogen acids (Hx)

Alcohols react with halogen acids to form alkyl halides.

$$CH_3OH + HCl \longrightarrow CH_3Cl + H_2O.$$

$$CH_3CH_2OH + HI \longrightarrow CH_3CH_2I + H_2O.$$

$$CH_3 - CH - OH + HCl \longrightarrow CH_3 CH - Cl + H_2O$$

 CH_3

$$CH_3 - C - OH + HCl \longrightarrow CH_3 - C - Cl + H_2O$$

$$CH_3 - C - CH_3 - C - Cl + H_2O$$

$$CH_3 - C - Cl + H_2O$$

Mechanism:

Primary and secondary alcohols follow SN_2 mechanism because of the fairly unstable carbon cation ion, while the tertiary alcohols follow SN_1 because of the stability of the carbon cation ion formed.

SN₂:

CH₃ CH₂
$$\ddot{O}H + H^{\delta +}$$
 $Cl^{\delta -}$ $l^{\delta -}$ Slow CH₃CH₂O⁺H₂ + Cl⁻

CH₃CH₂ -
$${}_{0}^{+}H_{2}$$
 $\xrightarrow{\text{fast}}$ CH₃CH₂ - Cl + H₂O $:$ Cl⁻

 SN_1 :

$$H - Cl \longrightarrow H^+ + Cl^-$$

$$CH_3$$
 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3

$$H^+ + \overline{O}H \longrightarrow H_2O.$$

PRACTICAL IMPORTANCE OF THE REACTION

The practical importance of the above reaction is to distinguish between the three classes of alcohol.

Reagent: An hydrous zinc chloride in concentrated hydrochloric acid.

Observation:

- An immediate cloudy solution at room temperature forms with a tertiary alcohol.
- Within 5 minutes at room temperature, a cloudy solution is formed with a secondary alcohol.
- No cloudy solution forms at room temperature with primary alcohol.

Equations:

REACTIONS WITH PHOSPHORUS HALIDES

Alcohols react with PX₅ and PX₃ to form alky halides where X is a halogen.

$$3CH_3CH_2OH + PCl_3 \longrightarrow 3CH_3CH_2Cl + H_3PO_3$$

$$CH_3CH_2OH + PCl_5 \longrightarrow CH_3CH_2Cl + HCl + POCl_3$$

Others: PI₃/PI₅

PBr₃/PBr₅.

NOTE:

Evolution of HCl or fuming whenPCl₅ is added to a compound suggests the presence of OH group in that compound.

REACTION WITH THINLY CHLORINE

Alcohols react with $SOCl_2$ or $SOBr_2$ to form alkyl halides. An organic base like pyridine must be included to neutralize toxic and poisonous gases liberated.

 $CH_3CH_2OH + SOCl_2$ pryridine $CH_3CH_2Cl + SO_2 + HCl$.

$$CH_2OH + SOBr_2$$
 $CH_2Br + SO_2 + HBr.$

Mechanism:

REACTION WITH H₂SO₄ ACID

Alcohols react with H₂SO₄ giving different products depending on the conditions of reaction.

Conditions:

- A. (i) Conc. H₂SO₄ Products got are substituted products.
 - (ii) Excess alcohol
 - (iii) Low temperatures.

 Substituted products.

 Alky hydrogen sulphate 0°C.

 Ether warm (140°C)
- B. (i) Conc. H₂SO₄.
 - (ii) High temperatures (heat) Elimination product.
 - (iii) Limited alcohol.

Example:

CH₃CH₂OH
$$\frac{Conc.H_2SO_4}{0^{\circ}c}$$
 CH₃CH₂HSO₄ + H₂O.

$$CH_2OH$$
 CH_2SO_4 $CH_2HSO_4 + H_2O.$

Phenyl methyl Hydrogen sulphate.

Mechanism:

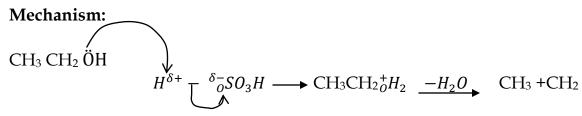

CH₃ CH₂
$$\stackrel{\delta}{O}$$
H

$$H^{\delta+} = \stackrel{\delta}{\int_{0}^{\delta}} SO_{3}H \longrightarrow \text{CH}_{3}\text{CH}_{2}^{+}H_{2} + \bar{O}SO_{3}H$$

CH₃ CH₂ $\stackrel{\delta}{O}$ H₂ $\stackrel{-H_{2}O}{\longrightarrow}$ CH₃ +CH₂ + H₂O.

CH₃ $\stackrel{\dagger}{\uparrow}$ CH₂ $\stackrel{\bullet}{\longrightarrow}$ CH₃CH₂HSO₄

Excess
$$2CH_{3}CH_{2}OH \xrightarrow{Conc.H_{2}SO_{4}} CH_{3}CH_{2}O CH_{2} CH_{3} + H_{2}O$$
Diethyl ethers
$$2CH_{3}OH \xrightarrow{Conc.H_{2}SO_{4}} CH_{3} O CH_{3} + H_{2}O.$$

[CH₃ CH₂ OH] >> $[\bar{O}SO_3]$ therefore CH₃CH₂OH is a better nucleophile.

CH₃ CH₂ÖH
$$^{+}$$
CH₃CH₂ \longrightarrow CH₃CH₂ - O - CH₂ CH₃ \downarrow $^{-}$ H⁺ CH₃CH₂ O CH₂ CH₃

Alcohols are dehydrated when heated with conc. H_2SO_4 and H_3PO_4 acid to form alkenes in a liquid phase or when the alcohol is passed over heated Al_2O_3 at 300° in a vapour phase.

Water molecule is eliminated and therefore this type of reaction is known as elimination or dehydration.

The reactivity in the liquid phase is determined by the type of carbon cation ion formed.

Elimination reactions occur under the following conditions:

(ii) Conc. H₂SO₄: [>60%].

Example:

CH₃CH₂CH₂OH
$$\frac{conc.H_2SO_4}{175-185^{\circ}C}$$
 CH₃ CH = CH₂ + H₂O

CH₃ CH CH₃
$$\xrightarrow{Conc.H_3PO_4}$$
 CH₃CH = CH₂ + H₂O OH

$$CH_3$$
 CH_3 CH_3
 $H_3C - C - OH$ $CONC.H_2SO_4$ $CONC.H_2SO_4$

$$CH_2 CH_2 OH \qquad Conc. H_3 PO_4 \qquad CH_2 = CH_2 + H_2 O.$$

CH3CH₂CH₂CH₂OH
$$\frac{conc.H_2SO_4}{175^o-185^oC}$$
 CH₃CH = CH CH₃ + H₂O.

CH₃ CH₂CH₂CH₃
$$\xrightarrow{Conc.H_2SO_4}$$
 CH₃CH = CH CH₃ + H₂O.
OH

Mechanism:

- 1. Protonation of alcohol
- 2. Loss of H_2O to form carbo cation ion.
- 3. Re-arrangement of the carbo cation to a more stable form.
- 4. Loss of the proton to form alkene.

$$CH_3$$
 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3 CH_3

$$CH_3$$
 $H_3C - C$
 CH_2
 CH_3
 $CH_$

CH₃CH₂CH₂CHOH
$$\frac{Conc.H_2SO_4}{175-185^{\circ}C}$$
 CH₃CH = CH CH₃ + H₂O

$$CH_3CH_2CH_2CH_2OH$$
 H^+ \longrightarrow $CH_3CH_2CH_2CH_2CH_2^+H_2$

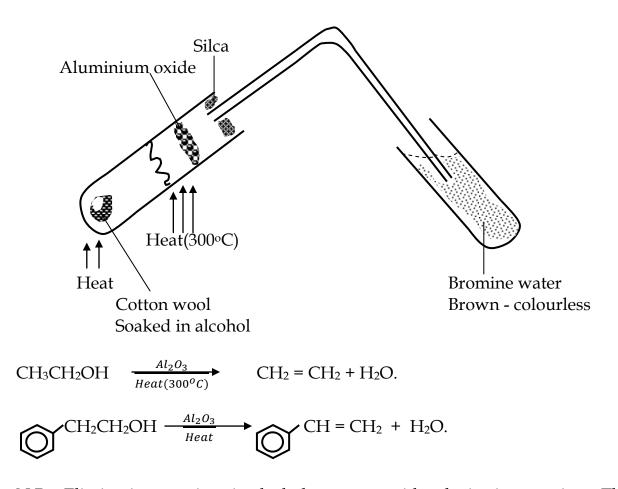

CH₃CH₂CH₂CH₂
$$\stackrel{\frown}{O}$$
H₂ $\stackrel{\frown}{O}$ H₂O CH₃CH₂CH₂+CH₂ + H₂O [Unstable(I $^{\circ}$ 1)]

CH₃CH +CH CH₃
$$\longrightarrow$$
 CH₃CH = CHCH₃ + H₂SO₄.

HO₃S $\overline{0}$:

DEHYDRATION IN VAPOUR PHASE

When an alcohol is heated and its vapour is passed over heated Al₂O₃ at 300°, an alkene is formed which is detected by turning bromine water colourless.

N.B: Elimination reactions in alcohols compete with substitution reactions. The difference is due to the conditions provided.

Conc.H₂SO₄(180°)

CH₂=CH₂ + H₂O

$$CH_3CH_2OH \longrightarrow CH_3CH_2OCH_2CH_3 + H_2O$$

$$Excess alcoho (140°)$$

OXIDATION REACTIONS

Secondary alcohol
$$[O]$$
 Ketones $[O]$ No product

Oxidation of alcohols is effected by oxidizing agents such as:

- (i) Acidified $K_2Cr_2O_7/H_{(aq)}^+$
- (ii) Acidified Na₂Cr₂O₇/ H^+ (aq)/ $Cr_2O_{7(qq)}^{2-}$
- (iii) Chromic acid, CrO₃.

Acidification is done by use of sulphuric acid.

$$CH_3CH_2OH + Na_2Cr_2O_7 + H_2SO_4 \rightarrow CH_3CHO + Na_2SO_4 + Cr_2(SO_4)_3 + H_2O_4 \rightarrow CH_3CHO + Na_2SO_4 + Cr_2(SO_4)_3 + H_2O_5 \rightarrow CH_3CHO + Na_2SO_4 + Cr_2(SO_4)_3 + H_2O_5 \rightarrow CH_3CHO + Na_2SO_5 + CH_3CHO + C$$

$$3CH_3CH_2OH + Na_2Cr_2O_7 + 4H_2SO_4 \xrightarrow{heat} 3CH_3CHO + Na_2SO_4 + Cr_2(SO_4)_3 + 7H_2O$$
Orange solution
$$(Cr_2O_7^{2-})$$
Green solution
$$(Cr^{3+})$$

During the process, the solution mixture turns from orange to green indicating the conversion of the dichromate to chromium(III) ion.

Excess oxidizing agent.

$$CH_3CHO + Na_2Cr_2O_{7(aq)} + H_2SO_{4(aq)} \rightarrow CH_3COOH + Na_2SO_{4(aq)} + Cr_2(SO_4)_3 + H_2O_{(l)}$$

Simply:

CH₃CHCH₃
$$\xrightarrow{H^+(aq)/Cr_2O_7^{2-}(aq)}$$
 CH₃ C CH₃ OH

CH₃OH
$$\xrightarrow{Excess H^+(aq)/Cr_2O_7^{2-}(aq)}$$
 HCOOH

CHO
$$\frac{H^+/Cr_2O_7^{2-}}{heat} \longrightarrow \text{COOH}$$

IODO FORM/HALO FORM TEST

This test is usually performed to confirm for the presence of compounds that have got a methyl group.

Example:

Methyl at dehydes
$$H_3C - C$$
O

Product formed CHI₃ - Tri iodo methane (Yellow ppt)

This test confirms / differentiates methyl / alcohols from the rest. Methy alcohols form tri iodo methane when oxidized which is observed as a yellow ppt, while the rest of the alcohols no observable change.

Reagent: Hot NaOH in Iodine solution.

Question: Give a reagent that can be used to distinguish between pairs of the compounds below and state what is observed in each case. Write the

equation for the reaction(s) that take place.

(a) CH₃CH₂OH and CH₃CH₂CH₂OH

Solutions:

(a) Hot sodium hydroxide solution.

With CH₃CH₂OH

- A yellow precipitate is observed.

With CH₃CH₂CH₂OH

- No observable change.

(b) Reagent: Hot sodium hydroxide in iodine solution.

With OH

- A yellow precipitate is observed.

CHCH₃

With OH

- No observable change.

CHCH₂CH₃

(c) Reagent: Hot sodium hydroxide in iodine solution.

With

QН

- A yellow precipitate is observed.

CHCH₃

With

ŌН

- No observable change.

CHCH₂CH₃

Equations:

 $CH_3CH_2OH + 4I_{2(aq)} + 6NaOH_{(aq)} + 6NaOH_{(aq)} + 6NaI_{(aq)} + 5NaI_{(aq)} + HCOONa^+ + 5H_2O.$

OH CHCH₃ +
$$4I_{2(aq)}$$
 + $6NaOH_{(aq)}$ heat CHI_{3(s)} + $5NaI_{(aq)}$ + $CO\bar{o}Na^+$ + $5H_2O$.

OH CHCH₃ +
$$3I_{2(aq)}$$
 + $4NaOH_{(aq)}$ heat CHI_{3(s)} + $OOODNa^+$ + $3H_2O_{(l)}$ + $3NaI$.

Rule: Alcohols; 4I2; 6NaOH

Aldehydes/ketones, 3I₂; 4NaOH.

Example:

O

$$| | | |$$

 $CH_3C CH_2CH_3 + 3I_{2(aq)} + 4NaOH_{(aq)} \rightarrow CHI_{3(s)} + CH_3CH_2COONa^+ + 3NaI + 3H_2O.$

AROMATIC ALCOHOLS

These are aromatic compounds with hydroxyl groups. They are divided into two: Aromatic alcohols and phenols.

(i) Aromatic Alcohols:

These contain an aromatic ring and then the hydroxyl group which is not directly attached to a ring but attached via the chain on the ring.

2-phenyl propan-2-ol

(ii) **Phenols:**

These contain an aromatic ring with one or more OH group directly attached to the ring.

PHENOLS

Is a class of compounds named as phenols and one or more OH groups are directly attached to the ring.

METHODS OF PREPARATION

1. Benzene sulphonic acid

Fuming
$$H_2SO_4$$

$$\begin{array}{c}
SO_3H \\
NaOH \\
\hline
SO_3^- Na^+ + H_2O
\end{array}$$

$$\begin{array}{c}
SO_3^- Na^+ + HCl_{(aq)} \\
\hline
O^- ONa^+ \\
\hline
O^- OH + NaCl.
\end{array}$$

2. Cumene process

3. **Aromatic halides**

In cumene process, Benzene is reacted with propene in presence of an acid or halogen carrier like AlCl₃ to form two phenyl propane.

Molecular O2 is blown into this product and the intermediate is acid hydrolysed to give a phenol.

When an aromatic halide is treated with alkali at extremely harsh conditions like 300°C, 200 atm of pressure and copper, a phenol is formed.

This subsequently strengthens the C – O bond by developing a partial double bond between C and C and at the same time weakening the O – H bond by decreasing the electron density and releases a proton easily. This does not occur in aliphatic aromatic alcohols as ordinary alcohols.

Subsequently, phenols being slightly acidic, under the following:

(i) Very soluble in NaOH or KOH

OH + NaOH
$$\overline{O}$$
Na+ H₂O

(ii) Phenols react with very reactive metals like Na to form salt and H₂.

OH
$$\bar{O}$$
Na⁺
2 $+$ 2Na_(s) $+$ H_{2(g)}

Acid properties of phenols can be improved by;

Adding electrons with a......which de-active the ring. Such groups include the Nitro groups. 2, 4, 6-trinitrophenol is more acidic than phenol. It liberates CO₂ from saturated NaHCO₃.

$$NaHCO_3 + O_2N \longrightarrow NO_2 \longrightarrow NO_2 + CO_2 + H_2C$$

$$NO_2 \longrightarrow NO_2$$

Carboxylic acids are more acidic than phenols. [Give the reactions that distinguish acidic character of phenols and carboxylic acids.

COMPLEX FORMATION WITH NEUTRAL FECL₃.

Phenols form a complex with aqueous neutral FeCl₃ and the colour of the complex product is violet colouration (purple). This reaction is important in confirming the presence of a phenolic group and it is also useful in distinguishing between phenol and aromatic alcohols.

Question: Distinguish between HCOOH and CH₃COOH. (We use the Iodo form test).

OR:

Using neutral (iron III) chloride) solution. A purple colouration with HCOOH. No observable change with CH₃COOH.

REACTION WITH ZICN DUST:

Phenol when heated with Zinc dust forms benzene.

ALCOHOL REACTIONS OF PHENOLS RESEMBLING

This involves cleavage of C - O bond.

Phenols undergo some reactions resembling alcohol where the C - O bond is involved.

Esterification:

Phenols react with carboxylic acids, halides and acid an hydrides to form an ester.

Carboxylic acids:

Acid halides:

Acid an hydride:

$$CH_3 \quad C - OC - CH_3 \quad + \quad \bigcirc OH \quad \longrightarrow OC CH_3 \quad + \quad CH_3 COOH$$

Ether formation:

Phenols react with alka oxides to form ethers.

$$\bigcirc OH + CH_3CH_2 \, \overline{O}Na^+ \longrightarrow \bigcirc OCH_2CH_3 + NaOH$$

Phosphorous penta halides:

Phenols react with PCl₅ liberating HCl gas which fumes in air.

$$\bigcirc OH + PCl_5 \longrightarrow \bigcirc Cl + POCl_3 + HCl$$

Reactions with liquid NH₃.

REACTIONS OF THE RING IN PHENOL

Due to the presence of the OH group in phenol, phenol undergoes a number of reactions where delocalized electrons on the ring are involved.

Nitration:

Phenol reacts with conc. H₂SO₄ and conc. HNO₃ acids to form 2-nitro phenol and 4-nitrophenol.

Alkylation:

Phenol reacts with alkyl halides in presence of a halogen carrier to form alkylated product phenol.

A cylation (O)

Bromine H₂O.

When reacted with bromine, H₂O phenol forms a substituted poly product of 2, 4, 6 tri bromo phenol which is a white precipitate.

The presence of OH makes phenol to be very reactive. This reaction is very important in confirming the presence of phenol together with the neutral iron (III) chloride test.

$$OH \longrightarrow Br \longrightarrow Br \longrightarrow Br \longrightarrow Br \longrightarrow Br \longrightarrow Br \longrightarrow Br$$

Hydrogen in presence of heated Ni catalyst.

Phenol can be hydrogenated into cyclo hexanol when reacted with H₂ in the presence of a heated catalyst.

$$\begin{array}{ccc}
OH & OH \\
\frac{3H_2/Ni}{heat(200^0)} & OH
\end{array}$$

POLYHYDRIC ALCOHOLS

These are alcohols with more than one OH group attached to the same carbon chain as:

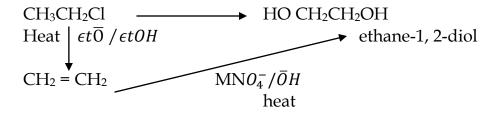

The chemical and physical properties of these types of alcohols are slightly the same; however, there are slight differences.

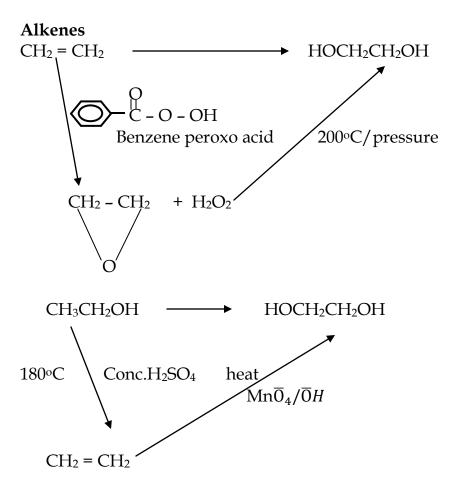

Ethane-1, 2-diol boils at a higher temperature.

Ethane-1, 2-diol has two OH group which results into formation of extensive hydrogen bonds which is difficult to break hence high boiling point.

PREPARATION OF DIOLS

They can be prepared from alkyl halides.

Reactions of diols are the same as those of monohydric alcohols. The difference is that excess of the reagent is used.

CH₃ CH₂ CH₂ OH

heat Conc.H₂SO₄

175°C

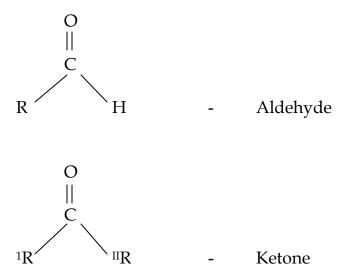

CH₃CH = CH₂

$$\frac{\text{heat}}{\text{Mn}\bar{o}_4/\bar{o}\text{H}} \text{CH}_3\text{CH CH}_2\text{OH}$$

CARBONYL COMPOUNDS

These are compounds containing a carbonyl functional group. They are alkanal (Aldehydes) and alkanones (Ketones).

These two belong to a group of organic compounds known as carbonyl compounds with a general formula $C_nH_{2n}O$.

The major difference between aldehyde and ketone is in the presence or absence of H₂ attached onto the carbonyl carbon.

In aldehydes, "H" is to the carbonyl carbon while in a ketone, similar or different alkly groups are attached to the carbonyl carbon as shown above.

NOMENCLATURE

IUPAC system is used in the naming of both aldehydes and ketones. Generally, aldehydes are named as alkanals by replacing "e" in the alkane name with -"als" while ketones are named as alkanones by replacing -"e" with -"ones".

(Formaldehyde)	Alkanals	Alkanones O
	HC - H Methanal	CH ₃ C CH ₃ Propan-2-ones
(Acetaldehyde)	O CH₃ C - H ethanol	O CH ₃ C CH ₂ CH ₃ butan-2-ones

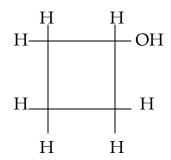

ISOMERISM

Both aldehydes and ketones exhibit structural and functional isomerism.

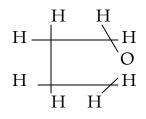

In structural isomerism, they show position and chain isomers.

In functional isomerism, both aldehydes and ketones are isomeric within themselves and with other classes of organic compounds like alcohols and cyclic ethers.

 C_4H_8O

Cyclic butanol (cyclic alcohol)

Cyclic ether (Tetacfuran)

 C_4H_8O

CH₃CH₂CH₂CHO

Butanal

CH₃CH - CHO CH₃ 2-methyl propanal (Aldehyde)

CH₃ C CH₂ CH₃

Butan-2-one (Ketone)

 $CH_2 - CH_2$ $CH_2 - CH_2$

Tetrahydrofuran (furan)

CH₂ = CH CH₂ - CH₂ OH

But-en-4-ol

(Usaturated alcohol)

Write all the isomers of the compounds with the molecular formula C_3H_6O . CH_3CH_2CHO Propanal (Aldehyde)

O CH₃ C CH₃

Propanone (Ketone)

$$CH_2 = CH CH_2OH$$
 Prop-1-en-3-ol.

PREPARATION OF CARBONYL COMPOUNDS

They can be prepared from the following:

- i) Mild oxidation of alkanol (alcohols)
- ii) Carboxylic acids or their salts.
- iii) Ozonolysis of alkenes followed by hydrolysis.
- iv) Acid hydrolysis of alkynes.
- v) Hydrogenation of acid chlorides.
- vi) Acylation (aromatic ketones)

OXIDATION OF ALCOHOLS

Primary and secondary alcohols are oxidized in liquid phase using $K_2Cr_2O_7/H^+$ or $Na_2Cr_2O_7/H^+$, CrO_3/H^+ to form aldehydes and ketones respectively.

During oxidation process, a colourless solution turns to green solution.

Examples:

CH₃CH₂OH
$$\xrightarrow{H^+/Cr_2O_7^{2-}(aq)}$$
 CH₃CHO $\xrightarrow{H^+(aq)/Cr_2O_7^{2-}}$ CH₃COOH
Alcohol Ethanal Carboxylic acid
Aldehyde

OH
CH CH CH₃ $\xrightarrow{H^+(aq)/Cr_2O_7^{2-}}$ CH₃ C CH₃

CH₂OH $\xrightarrow{H^+(aq)/Cr_2O_7^{2-}}$ CH₃ C CH₃

CH₂OH $\xrightarrow{H^+(aq)/Cr_2O_7^{2-}}$ CH₂OH $\xrightarrow{H^+(aq)/Cr_2O_7^{2-}}$ COO

During the oxidation process, especially for primary alcohols, there will be further oxidation to carboxylic acid which renders this method ineffective but this further oxidation can be avoided by carrying out a reaction under low heat (temperatures) or limiting the amount of the oxidant used.

Oxidation can also be effected under vapour phase. When an alcohol vapour is passed over heated Cu at 300°C, it is oxidized to an aldehyde or ketone.

$$CH_3CH_2OH_{(g)} \xrightarrow{Cu} CH_3CHO + H_2$$

$$CH_3 CH CH_3 \xrightarrow{300^{\circ}C} CH_3 C CH_3 + H_2$$

$$OH$$

Oxidation under vapour phase can also be brought about when an alcohol together with limited O₂ is passed over heated Ag at 500°C.

CH₃ CH₂OH +
$$\frac{1}{2}$$
 O₂ $\xrightarrow{Ag_{(S)}}$ CH₃CHO + H₂O

CH₃ C(OH) CH₃ + $\frac{1}{2}$ O₂ $\xrightarrow{Ag_{(S)}}$ CH₃ COCH₃ + H₂O

CARBOXYLIC ACIDS

When a carboxylic acid salt of calcium is heated, an aldehyde id formed. More specially methanol is formed.

$$Ca(COO)_2$$
 heat $CaCO_3$ + HCH

With other higher aldehydes, Ca salt of a carboxylic acid is heated with calcium methanoate.

Examples:

$$(CH_3COO)_2 Ca_{(s)} + (HCOO)_2 Ca_{(s)} \xrightarrow{heat} 2CH_3CHO + 2CaCO_3$$

Ethanal

$$(CH_3 CH_2 CO\overline{0})_2Ca^+ + (HCOO)_2Ca \xrightarrow{heat} 2CH_3CH_2CHO + 2CaCO_3$$

Propanal

$$(\bigcirc CO\overline{0})_2 Ca^+ + (HCOO)_2 Ca^- heat 2 \bigcirc CHO + 2CaCO_3$$

Benzaidehyde

Ketones can be prepared by heating Ca salts of higher carboxylic acids.

CH₃COCH₃ heat

OZONOLYSIS

When an alkene is reacted with ozone, an ozonide id formed. When the ozonide is diluted in H_2O in presence of some zinc, a carbonyl compound is formed. Zinc dust is used to decompose H_2O_2 .

Note: Aldehydes formed depends on the types of alkene used. Symmetrical alkene gives one type of aldehyde while unsymmetrical will give you both carbonyls.

$$CH_2 = CH_2 + O_3 \longrightarrow CH_2 CH_2$$

$$O - O$$

$$CH_2 CH_2 H_2O/Zn 2HCH + H_2O_2$$

$$CH_3CH = CH_2 + O_3 \longrightarrow CH_3 CH CH_2$$

CH₃ CH CH₃ + H₂O
$$Z_n$$
 CH₃CHO + HCHO + H₂O $O - O$

$$CH_3$$
 CH_3
 $C = C - CH_3 + O_3 \longrightarrow 2CH_3 CO CH_3$
 CH_3

$$CH_3$$
 $CH_3 C = CH CH_3 + O_3$
 $CH_3COCH_3 + CH_3CHO$

The above method has the disadvantage of yielding a mixture of products which may not be good in organic synthesis.

HYDROLYSIS (ACID) OF ALKYNES

When an alkyne is passed through hot H_2SO_4 in presence of mercury sulphate, the carbonyl carbon is formed.

CH
$$\equiv$$
 CH + H₂O $\xrightarrow{H_2SO_4/H_gSO_4}$ CH₃CHO Ethanal

$$CH_3C \equiv CH + H_2O \xrightarrow{\frac{H_2SO_4/H_gSO_4}{60^{\circ}C}} CH_3COCH_3$$

HYDROGENATION OF ACID CHLORIDES

Acid chlorides are reduced by hydrogen in presence of catalysts like pd to form aldehydes.

ACYLATION

Alkyl acylation is a reaction between acid halides with a benzene ring compound. This reaction produces aromatic ketones when it is carried out in presence of a halogen carrier (Al Cl₃, FeCl₃)

PHYSICAL PROPERTIES OF CARBONYL COMPOUNDS

Lower members of aldehydes and ketones are liquids and are miscible with H₂O forming neutral solutions. The miscibility in H₂O is due to the polar carbonyl carbon.

They have higher boiling points than their hydrocarbon counterparts. This is because of the polar nature of the carbonyl carbon that results into the intermolecular attractions but their boiling points are lower than those of alcohols and carboxylic acids due to the lack of H₂ bonding.

CHEMICAL PROPERTIES OF CARBONYL COMPOUNDS

Carbonyl compounds chemically react because of the property of the carbonyl carbon which is a common functional group present in both aldehydes and ketones.

A carbonyl carbon contains more electronegative oxygen bonded to carbon which pulls electrons towards itself and attains a δ^- charge while the carbon remains δ^+ . Therefore, the carbon oxygen bond is polarised creating a good condition for nucleophillic reagents to be added across the carbonyl carbon. The intermediate formed with a negative on oxygen reacts with an electrophille to form the final end product.

$$\delta + C = 0^{\delta -}$$

$$0^{\delta -}$$

$$C$$

$$-C - = -C -$$

$$Nu$$

$$Nu$$

Carbonyl group in aldehyde is more reactive than in ketones.

Explanation:

In ketones, the presence of two alkyl groups having a positive inductive effect highly neutralizes the positive charge in the carbon resulting into a less attraction of a nucleophile.

$$R - C - H$$

$$\delta +$$

$$R - C - R$$

$$\delta +$$

$$R - C - R$$

Methanol is more reactive than other aldehydes. Explain.

In methanol only hydrogen is bonded to the carbonyl carbon that the partial positive charge formed is not neutralized making methanol more reactive.

Therefore, the more number of alkyl groups added to a carbonyl carbon, the les the reaction due to the following reasons:

- The alkyl groups have got electron pushing (positive inductive) effect (i) which neutralizes the partial) positive charge on the carbon.
- (ii) Several alkly groups will have a crowding effect preventing a nucleophile from being attached to the carbon.

Order of the reactivity of the following:

When other atoms of a more electronegative effect are added next to the carbonyl group, the reactivity of the carbonyl carbon compound increases. E.g. if a hydrogen on the carbon atom next to the carbonyl group is replaced with a halogen, the reactivity increases.

$$\begin{array}{c|c} C & O^{\delta-} & Cl & O^{\delta-} \\ CH_3CH_2C-H & CH_3CH-C-H & CH_3C-C-H \\ & \delta + & Cl & Cl \end{array}$$

REACTION OF CARBONYL COMPOUNDS GENERAL REACTION (BOTH KETONES AND ALDEHYDES)

(i) Reactions of alkyl groups:

Both aldehydes and ketones containing alpha hydrogen i.e. hydrogens on the carbons next to be carbonyl group undergo halogenations reaction, when reacted with a halogen to form substituted products. Substitution proceeds until the alpha hydrogens are replaced.

CH₃CH + Cl₂
$$\longrightarrow$$
 CH₂Cl C - H + HCl

 \downarrow Cl₂
 \downarrow CHCl₂ CH + HCl

 \downarrow CH₃C CH₃ + Br₂
 \downarrow CH₂Br C CH₃ + HBr

 \downarrow Br₂
 \downarrow CH Br₂ C CH₃ + HBr

 \downarrow CH₃COCH₃ \downarrow Br₂
 \downarrow CH₃COCH₃ + 3Cl₂
 \downarrow CCl₃ CCH₃ + 3HCl

(ii) Reactions due to carbonyl group:

Both aldehydes and ketones containing a carbonyl group undergo the following reactions:

Reduction (Reaction with H₂)

Aldehydes and ketones are reduced by H₂ in presence of a suitable catalyst e.g. Ni/150°C, pt/pd into primary and secondary alcohols respectively.

CH₃CHO + H₂
$$\xrightarrow{Ni/150^{\circ}C}$$
 CH₃CH₂OH
CH₃COCH₃ + H₂ \xrightarrow{Pt} CH₃ CH CH₃

Using reducing agents:

Similarly strong reducing agents such as Aluminium, Na, Lithium tetrahydride, Na/Ethanol can also be used to effect reduction.

$$CH_3COCH_3$$
 $\xrightarrow{Li \ AlH_4}$ $CH_3CH(OH)CH_3$

Mechanism of reduction:

$$H_{2} \xrightarrow{Pt} H^{+} + :H^{-}$$

$$0^{\delta-} \qquad 0$$

$$0 \leftarrow H^{+} \qquad 0$$

$$CH_{3} C_{\delta+} CH_{3} \rightarrow CH_{3} - C - CH \rightarrow CH_{3} - C - CH_{3}$$

$$H^{-}: \qquad H$$

Addition of HCN (hydrogen cyanide)

Both carbonyl compounds react with HCNs to form 2 hydroxyl nitrates or cyanohydrins. The HCN is generated insitu from the reaction between NaCN and Conc. H₂SO₄.

$$OH$$
 $CH_3CHO + NaCN + H_2SO_4$

 CI
 $CH_3 COCH_3 + PCl_5 \longrightarrow CH_3 C - CH_3 + POCl_3$

CONDENSATION REACTIONS

Aldehydes and ketones react with compound containing amino groups to form condensations products and loss of H₂O molecule. These products formed have got sharp melting points which are used in identification of the original compounds.

These types of reactions are condensation because there is elimination of a H₂O molecule.

$$C = O + R - NH_2 \longrightarrow C = N - R + H_2O.$$

Polymerization:

i.e. nCH_3CHO Conc. $\overline{O}H$ CH₃(CH = CH)n CHO.

Reaction that distinguish between aldehydes and ketones.

Oxidation:

Aldehydes are oxidized by oxidizing agents e.g. $H^+_{(aq)}/K_2Cr_2O_{7(aq)}$ H^+/CrO_3 to carboxylic acid.

Ketones are resistant to oxidation and therefore they never yield any product with the same reagents.

Test:

Add 2 drops of an aldehyde into 2cm³ of H⁺_(aq)/K₂Cr₂O_{7(aq)} and warm.

An orange solution turns to green, the resultant solution becomes acidic.

CH₃ CHO
$$H^{+}_{(aq)}/Cr^{2}O_{7}^{2-}(aq)$$
 CH₃COOH + $Cr^{3+}_{(aq)}$ + $H_{2}O$.

Benedicts or Fehling's solution:

Increases a solution containing Cu^{2+} ions. This solution is blue in colour but when reacted with an aldehyde under heat, the aldehyde decreases Cu^{2+} to Cu^{+} resultant into a red-brown precipitate of $Cu_2O_{(s)}$.

This property of aldehyde is reduction.

Ketones do not give a red-brown precipitate.

$$CH_3CHO + Cu^{2+} + H_2O$$
 heat $CH_3COOH + Cu_2O_{(s)}$.

Ammoniacal silver nitrate (Tolleris reagents)

Ammoniacal silver nitrate solution is a solution of silver nitrate in NH₃.

Aldehydes unlike ketones are oxidized by this mild oxidizing agent to a carboxylic acid.

The Ag⁺ in the AgNO₃ is reduced to Ag metals. Therefore, the observation made in practicals is; a grey deposit or silvery coating on the sides of the test tube.

CH₃ CHO + Ag (NH₃)₂ NO₃ + H₂O_(l)
$$\xrightarrow{\text{heat}}$$
 CH₃CO $\overline{0}$ NH₄⁺ + Ag + NH₄NO₃.

Note that atmospheric O_2 can also oxidize aldehydes. This is why samples of aldehydes are normally contaminated when exposed to the atmosphere.

Iodoform / haloform reaction:

This reaction is only possible for methyl aldehydes and ketones. Since we have only one methyl aldehyde, ethanal, the reaction is strictly positive for ethanol and methyl ketones with the following structure.

Ethanal Methyl ketones
$$O$$
 C C C CH_3

The reaction is useful in practicals in determining the structure of carbonyl compounds.

Test:

When iodine and NaOH is added to ethanol or a methyl ketone and warmed, a yellow precipitate of tri iodo methane is formed.

$$CH_3CHO + I_{2(g)} + NaOH_{(aq)} \longrightarrow CHI_{3(s)} + NaI + HCOONa^+ + H_2O_{(l)}$$

O | CH₃C CH₃ +
$$I_{2(aq)}$$
 + NaOH_(aq) warm CHI₃ + CH₃COONa⁺ + NaI_(aq) + H₂O.

CARNIZARO REACTIONS:

This reaction is only possible for aldehydes withour ∝-hydrogen ketones.

When NaOH is reacted with an aldehyde without an alpha-hydrogen of general formula.

HCHO, CHO, the aldehyde is oxidized to carboxylic acid and the other half is decreased to the alcohol.

$$2$$
 CHO + NaOH \longrightarrow COOH + CH₂OH.

2HCHO NaOH → HCOOH + CH3OH.

Name the reagent that can be used to distinguish between the following pairs of compounds and in each case, state what would be observed when the reagent it separately treated with each compound.

(i) COCH₃ and COCH₂CH₃.

Reagent: Hot iodine solution in aqueous sodium hydroxide.

With COCH₃ : A yellow precipitate.

With \bigcirc COCH₂CH₃ : No observable change.

(ii) CH₃COCH₃ and HCHO Reagent: With CH₃COCH₃ With HCHO

(iii) CHO and COCH₂CH₃

Reagent:
With CHO

With COCH₂CH₃

(iv) CH₃CH₂COCH₃ and HCHO Reagent: With CH₃ CH₂ CO CH₂ CH₃ With HCHO

CARBOXYLIC ACIDS CARBOXYLIC ACIDS/ALKANOIC ACIDS

Carboxyclic acids are organic compounds with a general formula,

O R C - OH

 $(C_nH_{2n}O_2)$ if they are saturated. They contain two functional groups:

O Carbonyl carbon group

Carboxylic acid group

- OH - hydroxyl group

γ _C - O - H

Carboxylic acids can be roughly categorized into the following:

(i) Monobasic acid:

Contains a single carboxylic acid group.

O R C - OH

(ii) Diabasic acid

Contains two carboxylic acid groups joined to the same carbon chain.

(iii) Tribasic acid

Contains three carboxylic acid groups joined to the same carbon chain.

Nature of the alkyl group Saturated carboxylic acid

Contains the R group with single carbon-carbon bond.

Unsaturated carboxylic acid

Contains atleast a double bond in the alkyl chain.

$$H_2C = CHC - OH$$

Propenoic

Alkyl group.

NOMENCLATURE

According to the IUPAC system, carbonxylic acids are named after their corresponding alkanes. This is usually done by replacing a suffix-ane by OIC.

HCOOH Methanoic acid

CH₃COOH Ethanoic acid

CH₃CH COOH 2-methyl propan-1-oic

 CH_3

COOH Benzoic acid

COOH 3-hydroxy benzoic acid

CH₃CH = CH CHOO Buten-2-oic acid

CH₂ COOH 2-phenyl ethanoic acid.

HOOC-CH-COOH Butane-1, 2, 3-trioc acid.

 $CH_3(CH_2)_4 CH = CH - (CH_2)_2 COOH$ Dec-4-enoic acid.

MONOBASIC CARBOXYLIC ACIDS

These contain a single carboxylic acid group. They are largely found in nature. E.g.

Citric acid – in citrus fruits
Lactic acid (CH CH COOH)

Formic acid (HCOOH) - insect bites.

ISOMERISM

Monobasic acids show both structural and functional isomerism.

STRUCTURAL

Chain isomerism:

Isomers differ from nature of the carbon chain C₅H₁₀O₂.

CH₃CH₂CH₂COOH - Pentanoic acid

CH₂ CH₂ CH COOH - 3-methyl butanoic acid

CH₃ CH CH₂ COOH - 2-methyl butanoic acid CH₃

H₃C - C - COOH - 2, 2-dimethy propanoic acid

FUNCTIONAL

Monocarboxylic acids are isomeric with esters e.g. C₃H₆O₂

CH₃ CH₂ COOH O CH₃ C O CH₄

Propanoic acid Methyl ethanoate

METHODS OF PREPARATION OF MONOCARBOXYLIC ACIDS

Monocarboxylic acids can be prepared from the following:

(i) Oxidation of primary alcohola and aldehydes:

Primary alcohols are oxidized by excess oxidizing agents until carboxylic acids are formed.

Aldehydes are also oxidized to carboxylic acids.

Primary alcohol
$$\frac{Excess \ oxidising \ agent}{heat}$$
 carboxylic acid

Aldehydes
$$\frac{oxidising}{agent/heat}$$
 carboxylic acid

The main lab. Oxidizing agents used in this case are acidified $K_2/Na_2Cr_2O_7/H^+_{(aq)}/CrO_{3(aq)}, H^+_{(aq)}/KMnO_{4(aq)}$

CH₃ CH₂ OH
$$\xrightarrow{H^+(aq)/Cr_2O_7^{2-}(aq)} \rightarrow \text{CH}_3 \text{COOH}$$

CH₃ CHO
$$\frac{H^+(aq)/cr_2O_7^{2-}}{heat}$$
 CH₃ COOH

(ii) Hydrolysis of acid nitriles and acid amides with alkaline or acid.

When a nitrile is heated under reflux with mineral acid or alkali, an amide is first formed which later is further hydrolyzed to a carboxylic acid.

CH₃ C
$$\equiv$$
N $\xrightarrow{\frac{H^+/H_2O}{\bar{O}H/H_2O}}$ O CH₃ C - NH₂ H+/H₂O Ethanitrile Heat Ethanamide heat CH₃ COOH + NH₂

O

$$CH_3 CH_2 C NH_2 \xrightarrow{H^+/H_2 O} CH_3 CH_2 COOH + NH_3$$

Propanamide

The usefulness of this reaction is, increase of the carbon chain of one carbon. E.g. Convert $CH_2 = CH_2 \longrightarrow CH_3 CH_2 CH_2 OH$

CH₂ = CH₂
$$\xrightarrow{\text{HCl}}$$
 CH₃ CH₂Cl $\xrightarrow{\text{KCN/$\epsilon$tOH}}$ CH₃ CH₂ CN

CH₃ CH₂CH₂OH $\xrightarrow{\text{LiAlH}_4}$ CH₃ CH₂ COOH

(iii) From dicaboxylic acids

When dicarboxylic acids are heated, they are decomposed by loss of CO₂ to form a monocarboxylic acid. This reaction is important in reducing the carbon chain by one carbon.

COOH
$$\xrightarrow{160^{\circ}C}$$
 COOH $+ CO_2$

PROPERTIES OF CARBOXYLIC ACIDS

Physical properties:

Lower members $(C_1 - C_4)$ are colourless liquids very soluble in H_2O .

Medium members $(C_5 - C_9)$ are solids only partially soluble in H_2O .

SOLUBILITY OF CARBOXYLIC ACIDS IN H2O.

Solubility of carboxylic acids decreases with the increase in the carbon chain. This is because the more number of carbon chains which are hydrophobic outweighs the carboxylic acid group, which is responsible for forming H₂ bonds with H₂O hence low solubility.

Melting and boiling points:

Carboxylic acids show high values of melting and boiling points compared to their corresponding alcohols and alkanes. This is because a single molecule of a carboxylic acid dimerises via H₂ bonds which makes their melting and boiling points to be higher.

By them undergoing dimerisation, their apparent molecular masses when determined by **cryoscopic method** to be twice the actual molecular mass.

$$H_3C - C$$

O - H - - - O

C - CH₃

Apparent Mw = 120

Dimes

Real Mw = 60

The formation of H₂ bonds also make them to be very soluble in H₂O.

CHEMICAL PROPERTIES

Acid nature:

Carboxylic acids are acidic in nature. They are more acidic than phenol but less acidic compared to mineral acids. Aqueous solutions of carboxylic acids turn litmus paper red.

When dissolved in H₂O, they dissociate. An equation is established as shown.

$$R - C - OH + H2O \Longrightarrow R C - \overline{O}_{(aq)} + H3O+(aq)$$

$$Ka = \frac{[RCO\overline{O}][H3O+]}{[RCOOH]}$$
Moldm⁻³.

The Ka value is then used to denote the strength of the acid. The bigger the Ka value, the more stronger the acid.

Acid	Ka	PKa
Methanoic, HCOOH	1.77 x 10 ⁻⁴ mol dm ⁻³	3.75
Ethanoic, CH ₃ COOH	1.75 x 10 ⁻⁵ mol dm ⁻³	4.82

Another important value is PKa, therefore the higher the PKa value, the weaker the acid.

Explanation/reason for acid strength

Acidity of carboxylic acids is determined by a number of factors;

(i) Resonance of the carboxylic ion

When the carboxylic acid group ionizes, it forms the carboxylic ion and this ion may show several resonance structures in order to attain a more stable form. The more stable the carboxylate, the stronger the acid.

I, II and III are resonance structures of carboxylic acid.

(ii) Inductive effect:

Inductive effect is a tendency of an atom or groups of atoms to donate or withdraw electrons from a certain group.

Adjacent electron withdrawing substituents increase the acidity by further stabilizing the carboxylate. E.g.

Acids	Structure	PKa
Ethanoic acid	CH_3CO_2H	4.7
Fluoro ethanoic	FCH ₂ CO ₂ H	2.6
Dichloro ethanoic	ClCH ₂ CO ₂ H	1.3
Chloro ethanoic	Cl ₂ CHCO ₂ H	2.9
Tri-chloro ethanoic	Cl ₃ CCO ₂ H	0.9
Nitro ethanoic	NO ₂ CH ₂ CO ₂ H	1.7

The above table shows that the presence of an electron withdrawing atom pulls electrons from the bond decreasing electron density of that bond (O–H) and the ease of a proton release.

More atoms of such groups decreases the electron density of the O - H bond further and stabilizing the carboxylate thus high acidity.

The data below shows the PKa of the following acids. Explain.

Acid	PKa
CH ₃ COOH	4.7
CH ₃ CH ₂ COOH	4.9

REACTIONS OF CARBOXYLIC ACIDS

They react as weak acids.

They react with bases e.g. (KOH and NaOH) to form a salt and H₂O.

$$\begin{array}{ccccc}
O & O \\
R C - OH + NaOH & \longrightarrow & R \overline{CO}Na^{+} + H_{2}O.
\end{array}$$

$$CH_3CO_2H + OH \longrightarrow CH_3CO\overline{O}_{(aq)} + H_2O.$$

$$\bigcirc$$
 COOH + KOH \longrightarrow \bigcirc CO $\overline{0}$ K⁺ + H₂O

REACTION WITH SODIUM CARBONATE (NA₂CO₃)

Carboxylic acids unlike phenol react with Na_2CO_3 very slowly to liberate $CO_{2(g)}$. This reaction is of practical importance in distinguishing carboxylic acids from phenols. The reagent used is saturated Na_2CO_3 .

$$CH_3COOH + Na_2CO_{3(aq)} \longrightarrow 2CH_3COONa^+ + H_2O_{(l)} + CO_{2(g)}$$

Similarly, CO₂ can also be evolved from saturated NaHCO₃.

OTHER REACTIONS:

With SOCl₂.

Carboxylic acids react with SOCl₂ in presence of an organic base e.g. pyridine to form an acid chloride and SO₂. This is one useful way of preparing acid chlorides.

RCOOH + SOCl₂
$$\xrightarrow{\overline{tt}3N}$$
 O
R - C - Cl + SO_{2(g)} + HCl_(g)

Mechanism:

$$CH_3 - C - OH \longrightarrow CH_3 C - O - H$$

$$C = S - CI$$

$$C1 - S = O$$

Reaction with PCl₅.

Carboxylic acids react with PCl₃ or PCl₅ to form acid halides.

$$\begin{array}{ccc}
O & O \\
R C - OH + PCl_5 & \xrightarrow{RT} & R C Cl + POCl_3 + HCl
\end{array}$$

Reaction with alcohols

React with alcohols in presence of a mineral acid to form an ester under heat. This is called esterification where an ester is formed by refluxing a carboxylic acid and alcohol in presence of an acid catalyst.

To complete the reaction, one of the components either an acid or an alcohol has to be in excess or to remove an ester at a certain interval once it is formed.

CH₃ COOH + CH₃OH
$$\frac{H^+}{heat}$$
 CH₃ C O CH₃ + H₂O Methyl ethanoate

COOH + CH₃CH₂OH
$$\frac{H^+}{heat}$$
 C - OCH₂CH₃ + H₂O Ethyl benzoate COOH + OH $\frac{H^+}{heat}$ COOH + H₂O.

The mechanism for this reaction depends on the catalyst used/base catalysed or acid catalysed.

Acid catalyzed mechanism.

Reaction with amides:

Carboxylic acids react with amides to form substituted amines. With amines, they form amides.

CH₃COOH + (CH₃)₂NH
$$\longrightarrow$$
 CH₃ C N - CH₃ + H₂O CH₃

$$O$$
 $|$
 $CH_3 COOH + CH_3NH_2 \longrightarrow CH_3 C - NH CH_3 + H_2O$

COOH + CH₃ NH CH₃
$$\longrightarrow$$
 C - N - CH₃

This reaction occurs because of the presence of a proton on the amine which are substituted by the carboxylate.

Mechanism:

$$CH_{3} \begin{tabular}{ll} \hline O \\ \hline CH_{3} \begin{tabular}{ll} \hline CH_{3} \begin{tabul$$

REDUCTION OF CARBOXYLIC ACIDS

Carboxylic acids are usually reduced by reducing agents e.g. LiAlH₄/ether (THF) to form aldehydes and later alcohols (primary).

Note: *NaBH*₄ *is not commonly used to decrease carboxylic acids because it s less reactive.*

CH₃ COOH
$$\frac{Li Al H_4}{dry \ ether}$$
 CH₃CHO $\frac{Li \ Al \ H_4}{dry \ ether}$ CH₃ CH₂ OH + H₂O.

OR:

CH₃ COOH
$$\xrightarrow{Excess Li Al H_4}$$
 CH₃ CH₂ OH + H₂O

REACTIONS WITH HALOGENS (∝- HALOGENATIONS)

Carboxylic acids can be halogenated at the carbon atom adjacent to the carboxylic group when reacted with reagents like Br_2 , PCl_5 . This reaction depends on the character of the carbonyl compound where the product of the reaction known as α -bromo carboxylic acid, is converted to α -hydroxy or α -amino carboxylic acid.

O O
$$| | |$$
 CH₃ C OH + Br₂ PBr₃ BrCH₂- C - OH + HBr \propto -bromo ethanoic acid

$$\bigcirc$$
 CH₂ C OH + Br₂ $\xrightarrow{PBr_3}$ \bigcirc CH C OH + HBr.

DECARBOXYLATION

Carboxylic acids with a carbonyl group at the third position readily undergoes thermal decarboxylation where CO₂ is lost to form a simple alkane when heated in the presence of dry soda lime.

 Carboxylic acid derivatives

ACID HALIDES

These are compounds derived from carboxylic acids by reacting an acid with a halogen. The commonest examples are acid chlorides.

O
$$RC - X$$
 where $x =$ halogen atom.

Nomenclature:

Acid chlorides are named by replacing the suffix -ic in acids with -oyl.

PREPARATION

i) Reacting carboxylic acids with phosphorous halides.

$$CH_3COOH + PCl_3 \longrightarrow CH_3C Cl + H_3PO_3$$

ii) Reaction of carboxylic acid with thionyl chloride

This reaction should occur in a fume cupboard due to evolution of toxic acids or should occur in the presence of pyridine which absorbs.

$$O = C - Cl$$

$$COH + SOCl_2 \xrightarrow{Pyridine} heat + HCl + SO_2.$$

PROPERTIES OF ACID HALIDES

Physical:

They are colourless volatile liquids with irritating smells. They fume easily in moist air due to evolution of HCl gas.

Have low boiling points than the corresponding acids.

Chemical properties:

They undergo a number of reactions making them suitable for organic synthesis.

Hydrolysis using H₂O.

Acid halides react with H₂O to form their parent carboxylic acids.

$$\begin{array}{cccc}
O & & & O \\
CH_3 C Cl + H_2O & & RT & CH_3 C - OH + HCl
\end{array}$$

$$\bigcirc \stackrel{O}{\subset} CCI + H_2O \longrightarrow \bigcirc COOH + HCI$$

Reaction with alcohols:

Acid halides react with alcohols to form esters.

$$O$$
 $CH_3 \overset{\circ}{C} Cl + CH_3 OH \Longrightarrow CH_3 \overset{\circ}{C} O CH_3 + HCl$

Mechanism:

Mechanism:

$$CH_3 \overset{\circ}{C} - Cl \longrightarrow$$
 $H\overset{\circ}{O} CH_3 \overset{\circ}{C} - Cl \longrightarrow$
 $CH_3 \overset{\circ}{C} - Cl \longrightarrow$

Reaction with NH₃ and amines:

Acid chlorides react with NH₃ to form amides. This reaction is responsible with primary/secondary amines to form amides.

$$\bigcirc \stackrel{O}{\longleftarrow} \stackrel{O}{\longrightarrow} \stackrel{$$

CH₃ CH C Cl + NH₃
$$\longrightarrow$$

$$\bigcirc \stackrel{O}{\bigcirc C} C C I + NH_3 \longrightarrow \bigcirc \stackrel{O}{\bigcirc C} C - NH_2 + HCI$$
Benzanamide

$$O$$
 $CH_3 C Cl + CH_3 NH_2 \longrightarrow CH_3 C - NHCH_3 + HCl$

$$CH_3 C Cl + CH_3 NHCH_3 \longrightarrow CH_3 C N - CH_3 + HCl$$

$$O \qquad \qquad N, N-dimethyl ethanamide.$$

$$NH_2$$
 + $COCI$ + $N-C_1$ + HCI Phenyl benzanamide.

Reaction with benzene:

Acid halides react with benzene in presence of a hydrogen carrier.

$$\bigcirc + \bigcirc \stackrel{C}{\bigcirc} - Cl \xrightarrow{Al Cl_3} \bigcirc \stackrel{C}{\bigcirc} \bigcirc + HCl$$

$$CH_{3} \stackrel{\bigcirc{}}{C} \stackrel{}{C} \stackrel{\bigcirc{}}{C} \stackrel{\bigcirc{}}{C} \stackrel{\bigcirc{}}{C} \stackrel{\bigcirc{}}{C} \stackrel{\bigcirc{}}{C} \stackrel{\bigcirc{}}{C}$$

AMIDES

Amides are compounds derived from carboxylic acid and nitrogen containing compound like amine or NH₃ with a general formula

R C NH₂.

Unlike amines, they contain a carbonyl carbon directly attached to the nitrogen.

Naturally, such compounds are found in proteins.

Nomenclature:

Amides are named as derivatives of parent hydrocarbons alkane, replacing – e – amide.

E.g.

$$O$$

H C – NH_2 Methanamide

$$O$$
 CH_3 $C - NH_2$ Ethanamide

$$O$$
 $C - NH_2$
Benzenamide

PROPERTIES OF AMIDES

Physical:

All amides are colourless crystalline solids except ethanamide. They have got higher boiling points than corresponding carboxylic acids due to the formation of H₂ bonding.

PREPARATION

Reaction between acid halides and NH₃ or amines.

$$O$$
 $CH_3 \stackrel{\circ}{C} Cl + NH_3 \longrightarrow CH_3 \stackrel{\circ}{C} - NH_2$

$$\bigcirc C Cl + CH_3 CH_2NH_2 \longrightarrow \bigcirc C - N CH_2CH_3$$

$$\bigcirc H$$

Esters and ammonia

$$O$$
 $CH_3 C O CH_3 + NH_3$

 $NH_3 \longrightarrow N^+H_3 \longrightarrow CH_3 C - N^+H_3 + \bar{O}CH_3$
 $O H O H O H O CH_3 C - NH_2 + CH_3OH$
 $CH_3 C - N^+ - H \longrightarrow CH_3 C - NH_2 + CH_3OH$
 $CH_3 \bar{O}$:

With anhydrides

$$CH_3 \leftarrow OC - CH_3 \longrightarrow CH_3 \leftarrow CCO - CCH_3$$

$$NH_3 \qquad +NH_3 \qquad OCH_3 \leftarrow CH_3 \leftarrow CH_3 \leftarrow CH_3 \leftarrow CCH_3 \leftarrow$$

$$CH_3C \xrightarrow{N-H} CH_3C - NH_2 + CH_3C - OH$$

$$CH_3C - \overline{0}$$

$$CH_3C - \overline{0}$$

Amides are reduced by reducing agents such as sodium tetrahydride borate, LiAlH₄.

Hydrolysis

Amides are hydrolysed in presence of a mineral acid or an alkali to form a carboxylic acid.

For example:

CH₃ CH₂ C NH₂ + H₂O
$$\xrightarrow{H+/\bar{0}H}$$
 CH₃CH₂ COOH + NH_4^+

CH₃ O CH₃ CH₃ CH₃ CH₃ CH₃ CH₄ CH₄ CH COOH +
$$NH_4^+$$

For distributed amides, hydrolysis produces a carboxylic acid and on amine.

Example:

O

$$| | |$$
 $CH_3 C NH CH_3 \xrightarrow{H_2O/H^+} CH_3COOH + CH_3 NH_2$
N-methyl ethanamide
Primary amine
For trisubstituted.

CH₃ CON (CH₃)₂ + H₂O
$$\xrightarrow{\overline{O}H}$$
 CH₃COOH + NH(CH₃)₂
N-N-dimethylethanamide Secondary amine.

$$NH_3 + H^+ \longrightarrow NH_4^+$$

HOFFMAN'S DEGRADATION

When an amide is heated with Br₂ and an alkali, a primary amine id produced which is less than one carbon from the original amide; this reaction is known as Hoffman's degradation because it involves reduction of the carbon chain by one carbon atom.

(i)
$$O$$
 $CH_3 C NH_2 \xrightarrow{Br_2/KOH} CH_3NH_2$

Equation:

O | CH₃ C NH₂ + Br₂ + 4KOH_(aq) heat
$$\rightarrow$$
 CH₃ NH₂ + K₂ CO₃ + 2KBr + H₂O.

(ii) O
$$C - NH_2$$
 $\frac{Br_{2(aq)}/4\bar{0}H(aq)}{heat}$ $NH_2 + CO_3^{2-} + 2H_2O + 2Br^{-}$

ESTERS

Esters are derivatives of carboxylic acids. Are highly volatile compounds with a fruity smell. They conform to a general formula: O RC - O - R

NOMENCLATURE

Esters are named using their parent acid name but adding the suffix -ate.

$$\begin{array}{ccc} O \\ || \\ CH_3 \ CH_2 \ C \ O \ CH_3 \end{array} \quad \text{-} \quad \text{methyl propanoate} \\ \end{array}$$

$$O$$
 $| | |$
 $CH_3 O C CH_3 CH_2 CH_3$ - methyl butanoate

$$O$$
 || CH₃ C - O CH₂ CH₃ - ethyl methanoate

Isomerism

Esters show structural isomerism and functional isomerism. Functionally esters are isomeric with carboxylic acids.

C₄H₈O₂ CH₃CH₂COOH - Alcohol

PREPARATION OF ESTERS

(i) Esterification:

From carboxylic acids and an alcohol. This reaction is catalyzed by a mineral acid or an alkali.

$$CH_3 COOH + CH_3OH \xrightarrow[heat]{H^+} CH_3 COCH_3 + H_2O$$

OH + CH₃ COOH
$$\frac{H^+}{\text{heat}}$$
 O C CH₃ + H₂O Phenyl ethanoate

Mechanism:

From acid chlorides and acid anhydrides

When alcohols are reacted with acid chlorides or acid anhydrides, an ester is formed.

REACTIONS OF ESTERS

Esters undergo the following reactions:

i) **Hydrolysis**

Esters are hydrolyzed in presence of a mineral acid to a corresponding carboxylic acid and alcohol.

$$\begin{array}{c}
O \\
| \\
CH_3 C O CH_2 CH_3
\end{array}
\xrightarrow{H^+/H_2 O}$$

$$\begin{array}{c}
H^+/H_2 O \\
heat
\end{array}$$

$$\begin{array}{c}
CH_3 COOH + CH_3 OH
\end{array}$$

$$\bigcirc C - O CH_3 + H_2O \xrightarrow{H^+} COOH + CH_3OH$$

NOTE:

NOTE:
Hydrolysis involves cleavage at

O
R - C - O - R

The position of this cleavage is useful in radiolabelling to trace for the reaction mechanisms.

Example:

O

$$R \overset{1}{C} - {}^{18}_{0} - R + H_{2} \overset{16}{0} = R \overset{1}{C} - {}^{16}_{0}H + R - {}^{18}_{0}H$$

ii) Reduction

Esters are reduced with LiAlH₄ in presence of ether to carboxylic acid and the alcohol.

Example:

$$C - O CH_2 CH_3 \xrightarrow{LiAlH_4} CH_3CH_2OH + COOH$$

iii) Reaction with NH₃

Esters react with NH₃ to give amides and alcohols.

Example:

$$O$$
 $CH_3 CH_2 C O CH_3 + NH_3 \xrightarrow{heat} CH_3 CH_2 C - NH_2 + CH_3OH$

iv) Reaction with primary amines

AMINES

These are compounds that are derived from ammonia base by replacing one hydrogen with an amino group. They therefore have a general formula. $RCH_2 - NH_2$.

The functional group of amines is $-NH_2$ (amino group).

NOMENCLATURE

Amines are named as derivatives of alkanes by adding amine suffix to the stem name.

 $\begin{array}{ll} CH_3NH_2 & \text{methyl amine} \\ CH_3CH_2NH_2 & \text{ethyl amine} \\ CH_3CH_2CH_2NH_2 & \text{propyl amine} \end{array}$

NH₂ phenyl-amine (aniline)

CH₂NH₂ phenyl methyl amine

CLASSES OF AMINES

Amines are classified into four groups or four classes.

i) Primary amines

Is formed when only one hydrogen is replaced from the NH₃.

CH₃CH₂NH₂ Ethyl amine

NH₂ Phenyl amine (primary aromatic)

ii) Secondary amines

Is formed when two hydrogens of NH₃ are replaced by alkyl or anyl groups.

(CH₃)₂NH Dimethyl amine or N-N-dimethyl amine

CH₃NHCH₂CH₃ Ethyl methyl amine

NHCH₃ Phenyl methyl amine

iii) Tertiary amines

Are formed when all the hydrogens in the NH₃ are replaced by the alkyl group.

(CH₃)₃N Trimethyl amine

(CH₃)₂NCH₂CH₃ Phenyl dimethyl amine.

iv) Quartenary amines

Are salts formed when the lone pair on the Nitrogen is donated to an alkyl group.

$$(CH_3)_3$$
 $^+_NCH_3$

Tetramethyl amine.

Isomerism

Amines exhibit all the three types of isomerism, chain, positional and functional.

Write all isomers of $C_4H_{11}N$.

1. CH₃ CH₂ CH₂ CH₂ NH₂ n-butylamine

2. CH₃ CH CH₂ NH₂ 2-methyl propylamine CH₃

3. CH_3 CH₃ CH₃ CH₃ CH₃ 2-amino-2-methyl propane. CH₃

4. CH₃ CH₂ CH CH₃ 2-amino butane

1 and 2 are chain isomers. 3 and 4 are position isomers.

H5. $CH_3 CH_2 N CH_2 CH_3$ N-diethyl amine (functional)

6. CH₃
CH₃ N CH₂ CH₃ (Functional)

METHODS OF PREPARATION

From alkyl halides

When alkyl halides are heated with NH₃ in a sealed tube at a temperature of 100°C, the reaction gives a mixture of amines. This method is not suitable for producing a specific amine because of a mixture of amines.

Although the products produced may be controlled by using excess NH₃ and at the same time separating each product by functional distillation.

CH₃ CH₂ Cl + NH_{3(l)}
$$\xrightarrow{sealed\ tube}$$
 CH₃ CH₂ NH₂ + HCl. Primary

CH₃ CH₂ NH₂ + CH₃ CH₂ Cl $\xrightarrow{sealed\ tube}$ (CH₃CH₂)₂NH + HCl Secondary

$$(CH_3CH_2)_2NH + CH_3CH_2C1 \xrightarrow{sealed\ tube}$$
 $(CH_3CH_2)_3N + HC1$
Tertiary

NOTE:

When excess NH₃ is used,

CH₃ CH₂ Cl +
$$\frac{Excess}{NH_3}(l)$$
 $\frac{sealed\ tube}{100^{\circ}C}$ CH₃ CH₂ NH₂ + HCl

Mechanism:

Excess NH₃

$$H++Cl^{-}\longrightarrow HCl.$$

From alkyl cyanides

When an alkyl cyanide also known as a nitrile is reduced with reducing agents such as LiAlH₄ or NaBH₄. Or simply sodium in an alcohol, dry ether a primary amine is formed.

$$CH_3 C \equiv N \xrightarrow{LiAlH_4} CH_3 CH_2 NH_2$$

Ethanitrile

$$CH_3 CH_2 CN$$
 \xrightarrow{Na}
 $CH_3 CH_2 CH_2 NH_2$
Propanitrile

Benzenitrile

From acid amides

When an acid amide is reduced using reducing agents like LiAlH₄/dry ether, primary amines are formed.

CH₃ C NH₂
$$\xrightarrow{LiAlH_4}$$
 CH₃ CH₂ NH₂ + H₂O

CH₃
$$\overset{\text{O}}{\text{C}}$$
 - NHCH₃ $\xrightarrow{\text{LiAlH}_4}$ CH₃ CH₂ NHCH₃

HOFFMAN'S DEGRADATION

When amines are reacted with Br₂ in a solution of KOH or NaOH, a primary amine is formed which is one carbonless from the parent amide. This reaction shortens the chain by one carbon and it is known a Hoffman's degradation.

From nitro compounds

When a nitro compound preferably aromatic nitro compound is reacted with tin in conc. HCl or LiAlH₄/ether, aromatic amine is formed.

NO₂

$$Sn_{/HCl}^{Conc.}$$

$$heat (reflux)$$
NO₂

$$NH_2 + H_2O$$

$$NO_2$$

$$NH_2 + H_2O$$

$$NH_2 + H_2O$$

This method is suitable for preparing aromatic amines.

HYDROLYSIS OF TERTIARY AND SECONDARY AMINES

This produces primary and secondary amines respectively. When they are heated with mineralized acid H₂O or a base.

CH₃ NH CH₃ + H₂O
$$\xrightarrow{H^+}$$
 CH₃OH + CH₃ NH₂
Secondary Primary

$$CH_3 CH_2N(CH_3)_2 + H_2O \xrightarrow{H^+} CH_3 CH_2OH + CH_3NHCH_3$$

Tertiary Secondary

$$CH_3CH_2NHCH_3 + OH \xrightarrow{H^+} CH_3 CH_2 NH_2 + CH_3OH$$

Mechanism: (Base catalysed)

PHYSICAL PROPERTIES OF AMINES

- i. Lower amines up to C_2 are gases while those with $C_3 = C_{11}$ are liquids, higher amines are solids at room temperature.
- ii. Lower amines have got a fishy ammoniacal smell or odour.
- iii. Boiling points of amines are higher than those of corresponding alkanes.
- iv. Lower members are soluble in H₂O but the solubility decreases with increase in molecular weight.

Explanations for boiling points and solubility

Question:

Methyl amine CH ₃ NH ₂	Molecular 31	Boiling point °C -7
CH ₃ CH ₃	30	-89

Methyl amine boils at a high temperature than ethane because of the presence of intramolecular hydrogen bonding which holds methylamine molecules together in the liquid phase and difficult to escape to vapour phase during boiling and more heat required to boil while in ethane, the weak Van der Waal's forces are easily broken and loss heat required to boil.

Comparing three classes of amines, primary amine boils at a higher temperature than the secondary followed by tertiary.

Amine CH ₃ CH ₂ CH ₂ NH ₂	Molecular weight 59	Boiling point °C 49
CH ₃ CH ₂ NH CH ₃	59	35
CH ₃ - \ddot{N} - CH ₃ CH ₃	59	3.5

Primary amine forms atleast two intramolecular hydrogen bonding due to the presence of more hydrogen atoms on the nitrogen and hence boiling at a higher temperature.

The secondary amine forms only one hydrogen bond since it has only one hydrogen in the nitrogen while the tertiary amine has not hydrogen on the nitrogen and therefore forming no hydrogen bonding and ends boiling at the lowest temperature.

Assignment (Research work)

Carboxylic acids boil at higher temperatures than alcohols which also boils at a higher temperature than an amine and an alkane has the least boiling point. Explain.

BASICITY OF AMINES

Amines are bases which form weak alkaline solutions when dissolved in H_2O . Such solutions turn litmus paper to blue.

The basic strength of an amine is determined by the extent of ionization denoted as Kb. The greater the Kb value, the more basic the amine. The basic character of an amine can be explained by the presence of lone pair of electrons on the nitrogen atom which are always donated.

The more available these lone pair of electrons are, the more basic an amine is.

The availability of electrons on the nitrogen atom is determined by the atoms that are bonded onto it.

Groups of atoms that have got positive inductive effect will push electrons towards nitrogen making them available while those with negative inductive

effect will lower the electron density on the nitrogen atom making them less available.

$$CH_3 NH_2 + H_2O \implies CH_3 ^+_N H_3 + OH$$

$$Kb = \frac{\left[CH_3 + H_3\right]\left[\overline{O}H\right]}{\left[CH_3 + H_2\right]}$$

Questions:

- 1. Methylamine is a more stronger base than ammonia.
- 2. Phenylamine is a weaker base than methylamine.
- 3. Ethylmethylamine is a stronger bases than trimethyl amine.

Trend:

Secondary amine > Primary > Tertiary > ammonia

4. Amino benzene is a weaker base than aliphatic primary amine. Explain.

The final of Basicity will be;

Being basic amines, they react with mineral acids to produce salts. These salts are strong electrolytes because they fully get ionized and their pH is slightly less than 7.

1.
$$CH_3CH_2NH_2 + HCl \implies CH_3 CH_2 + H_3 + Cl$$

$$CH_3 CH_2 + H_3 Cl \implies CH_3 CH_2 + H_3 + Cl$$

$$CH_3 CH_2 + H_3 + H_2O \implies CH_3 CH_2 + H_3O + Acidic$$

$$\bigcirc \stackrel{\dagger}{\text{N}} \text{H}_3 \quad + \text{H}_2 \text{O} = \bigcirc \stackrel{\text{NH}_2}{\text{N}} \text{NH}_2 \quad + \text{H}_3 \text{O}^+$$

REACTIONS OF AMINES

1. With nitrous acid:

Nitrous acid being liable is generated insitu. Primary amines react with nitrous acid to form a colourless solution of alcohol and a colourless gas of nitrogen.

$$CH_3CH_2NH_2$$
 $NaNO_2/Conc.HCl$ $CH_3CH_2OH + N_{2(g)} + H_2O.$

Secondary amines will produce a yellow oily substances known as nitroso amines.

Tertiary amines when dissolved in HNO acid to form NH₄NO₂ which when warmed forms a nitrosoamine and an alcohol by decomposition.

$$(CH_3)_3$$
 ⁺_NH NO_2 Warm $(CH_3)_2N$ -N=O + CH_3OH Diethyl nitrosoamine.

Aromatic primary amines react with nitrous acid giving different products depending on the temperatures.

At temperatures below 10°C, aromatic primary amines with nitrous acid to form diazonium salts.

$$NH_2 \xrightarrow{NaNO_2/_{HCl}^{Conc.}} NH_2$$

Benzene diazonium chloride.

$$NH_2 \xrightarrow{NaNO_2/HNO_3} \begin{picture}(200) \put(0.00){N} $

At temperatures above ten (>10°C), the major product formed is a phenol.

$$NH_2 \xrightarrow{NaNO_2/_{HCl}^{Conc.}} OH + N_{2(g)} + H_2O_{(l)}$$

The above reaction is of practical importance in distinguishing the classes of amines.

In summary:

i) 1º amines : Yield a colourless solution and effervescence of a

colourless gas.

ii) 2° amines : Yield a yellow oily substance which when phenol and

conc. H₂SO₄ is added and the mixture made alkaline.

This yields an *intense blue colour*.

iii) 3° amines : A yellow oily substance persists.

iv) Aromatic amine : A brightly coloured compound known as an azo

dye is produced when 2-napthol (OO OH) is

added.

2. Reactions with acid chlorides and acid anhydrides.

1º and 2º amines react with acid chlorides and acid anhydrides to form amides.

Mechanism:

$$CH_{3} CCI \longrightarrow CH_{3} C-CI \longrightarrow CH_{3} C-+N$$

$$H-N-H \qquad H$$

$$CH_{3} C-N- \bigcirc$$

3. Reactions with sodium metal

Amines react with Na when heated to produce H_2 . This reaction is only possible with 1° and 2° amines which do have H_2 . The tertiary ones without H_2 do not.

$$CH_3 CH_2 NH_2 + Na$$
 heat $CH_3 CH_2 NH Na + \frac{1}{2} H_2$

$$(CH_3CH_2)_2NH + Na$$
 heat $CH_3CH_2 Na + \frac{1}{2} H_2$

4. Reactions with alkyl halides

Aromatic and alkyl amines react with alky halides to form higher amines.

CH₃NH₂ + CHCl
$$\longrightarrow$$
 NH₃NHCH₃ + HCl
CH₃NHCH₃ + CH₃ CH₂ Cl \longrightarrow (CH₃)₂N CH₂ CH₃ + HCl
 \bigcirc NH₂ + CH₃Cl \longrightarrow NH CH₃ + HCl

DIAZONIUM SALTS

These are salts formed from primary aromatic amine when reacted with an inorganic mineral acid. The process of forming these salts is diazotization.

Temperature is critical in the formation of a diazonium salt and the temperature always has to be $<10^{\circ}$ C. Where X is the halogen or $N0_{3}^{-}$, $HS0_{4}^{-}$.

Benzene diazonium chloride.

$$NaNO_2$$
 $Conc HCl$

$$NH_2 \xrightarrow{NaNO_2 \atop Conc.HCl} NH_2 \xrightarrow{NaNO_2 \atop Conc.HCl} NCl^-$$

What determines the anion is the acid used.

Nomenclature

Diazonium salts are named as benzene diazonium.

$$H_3C$$
 \longrightarrow NCl^- 4-methyl benzene diazonium chloride.

$$NO_2^+\equiv NCl^-$$
 2-nitro benzene diazonium chloride.

$$H_3C$$
 \longrightarrow $^+_N\equiv$ NNO_3^- - 4-methyl-2-nitro-benzene Diazonium nitrate. NO_2

$$H_3C$$

$$\begin{array}{c} \downarrow \\ NNO_3^- \\ \hline \\ CH_3 \end{array}$$
3, 5-dimethyl benzene diazonium Hydrogen sulphate.

Physical properties of diazonium salts

Are a colourless crystalline solids which turn brown on exposure to air.

Their solutions are neutral to litmus but very soluble in H₂O to give an ionic solution that has got good electrolytic conductivity.

Chemical reactions

Diazonium salts are very useful in organic synthesis reacting with different substances to form different products.

Coupling reaction

Benzene diazonium salts react with phenols to form brightly coloured compounds known as azo compounds by adding an aromatic ring to the nitronium ion a reaction known as coupling.

$$Ar - N = N - Ar$$
 or $N = N$

$$Azo compounds.$$

For coupling to occur, the aromatic ring must have a strong electron releasing groups such as hydroxyl, NH₂ – (amino), OR group and NHR group.

These groups will activate the ring making the electrons available at the para position for diazotization.

If the para position is already occupied, then diazoti-phenol.

OH +
$$N = N$$
 + HCI
Phenyl amine p-hydroxyl azo compound

$$NH_2$$
 + H_2N $N=N$ + $HC1$ p-amino azo compound.

2-naphol OH +
$$\bigvee_{N}^{+} \equiv NCl^{-}$$
 N= N $\bigvee_{N}^{+} \equiv NCl^{-}$ HO (Bright red solid) + HCl 2-napthol azo compound.

$$CH_3$$
 + CH_3 + CH_3 $N = N$ CH_3 $N = N$

1, 4-dimethyl benzene.

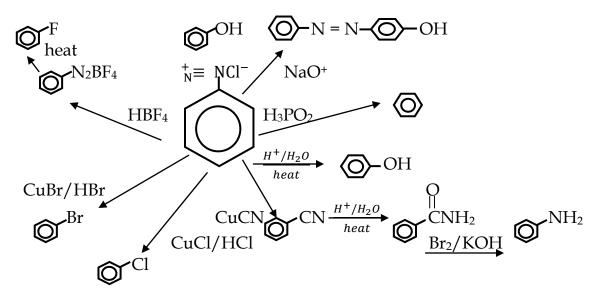

The importance of coupling

- i) Test for primary aromatic amines:
 - If a primary aromatic amine is treated with a mixture of NaNO₂ and HCl, 2-napthol, a bright red solid is formed due to the reaction of diazonium salt with 2-napthol at a temperature below 10°C.
- ii) It is used in preparation of dyes (coloured compounds) e.g. methyl orange indicator is prepared by coupling 4-hydrogen sulphite benzene, diazonium chloride and dimethyl phenyl amine.

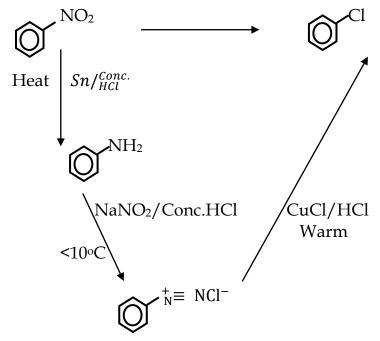

$$HO_3S \longrightarrow N \equiv NCl^- + \bigcirc N(CH_3)_2$$

$$HO_3S - N = N - N(CH_3)_2 + HCl$$

Methyl orange.

Convert Nitro benzene to chloro benzene

APPLIED ORGANIC CHEMISTRY

- 2. Lipids Soap and detergents
- 3. Hydro carbon petroleum

POLYMER AND POLYMERISATION

Definition:

A polymer is a compound of high molecular mass made up of small repeated units known as monomers. These molecules are formed by a process known as polymerization.

Polymerization is process of combining low molecular weight molecules repeatedly in some regular manner to forma high molecular mass compound. In polymerization, the low molecular mass molecules are always known as monomers.

These are simple molecules which when combined can form a dimer, trimer or a polymer when many.

POLYMERS:

There are two types of polymers depending on how they are formed.

i) Natural polymers

Are naturally occurring polymers not made by man e.g. cotton, wool, protein, rubber, starch e.t.c.

ii) Artificial polymers (Synthetic)

These are man-made polymers.

Example: Polythene Poly vinyl chloride (PVC)

Polyester Terylene

Nylon e.t.c.

Advantages of synthetic polymers over natural

- They can be produced in large quantities within a short period of time.
- Are recyclable
- Have got improved properties e.g. cross linkages for toughness, high density for tensile strain.

Advantages of natural polymers over artificial polymers

- They are biodegradable
- They are cheap since no process involved in producing them.

Properties of polymers

A polymer is judged by some of these properties:

i) The length of a polymer

This determines its strength and the melting point. The longer the length, the stronger the polymer would be and a high melting point it will have.

ii) Cross linkages

A cross link is a force that joins molecules within a polymer. When a polymer has got several cross linkages, it will have an increased strength.

iii) Branching

Increased branches within a polymer decreases its strength and lowers its melting point.

iv) Intermolecular forces

If a polymer has got several intermolecular forces within itself, then it will have increased strength than when there are few intermolecular forces.

CLASSIFICATION OF POLYMER

There are several ways of classifying polymers:

i) Addition polymers

These are polymers made by directly adding monomers without loss of any simple molecule.

Example:

$$n CH_2 = CH_2 + CH_2 = CH_2$$
 (ethene) $CH_2 - CH_2 - CH_2 - CH_2$ Polymer (Polythene)

ii) Condensation polymers

These are polymers made by combining monomer units but splitting out a small molecule which is usually H₂O. E.g. Terylene

PET (Polythene terathalein)

iii) Thermoplastic polymers

These are polymers that can soften and flow when heated and harden when they cool. In other words, they can be remolded into any shape by heat. E.g. polythene.

iv) Thermosetting polymers

these are polymers which when heated cannot melt but instead burn away. Such polymers cannot be remolded since they are initially set to a solid. E.g. Formica.

Other terminologies include:

i) Copolymer

A copolymer is a type of polymer made by having one or more different monomers. E.g. SBR (Styrene Butadiene Rubber). This is made from styrene and buta-1, 3-diene.

ii) A fibre

Is a form of polymer consisting of strings or bundles of strings that settle up during its formation.

iii) Elastomers

Is a type of polymer which when stress is applied, and released, it springs back to its original position e.g. rubber.

ADDITION POLYMERIZATION

Addition polymers

Definition: Addition polymerization

Examples:

Monomers	Formula	Polymer and trade	Uses
		name	
Ethene	$CH_2 = CH_2$	Polythene	Making bags, squeeze
(ethylene)		(Polyethylene)	bottles, films, toys,
			moulded objects,
			shoes, electrical
			insulators e.t.c.
Propene	$CH_3CH = CH_2$	Poly propene	Making bottles, films,
(propylene)		(polypropylene)	indoor and outdoor
, ,		(Vectra)	carpets.

Polypropene is formed when propene is heated at various pressures and catalytic temperatures.

$$CH_{3}CH = CH_{2} + CH_{3}CH = CH_{2} \xrightarrow{\begin{array}{c} high \ temperatures \\ catalyst \\ high \ pressure \end{array}} \begin{array}{c} CH_{3} \\ \\ CH - CH_{2} \\ \\ \end{array}$$

$$(Polypropene)$$

Vinyl chloride	CH ₂ = CHCl	Poly vinyl	- Making of floor
(Chloroethene)		chloride (PVC)	tiles.
			- Making pipes,
			raincoats,
			insulator tapes.

By modifying ethene, several polymers with better properties can be formed by adding groups of atoms with either -OH group (polar) or (non polar, giving polymers such as poly viny alcohol and polystyrene respectively. i.e.

$$n \ CH_2 = CH \qquad \xrightarrow{\underline{high \ temperature/high \ pressure}} \qquad CH_2 - CH \qquad n$$

$$(Poly \ viny \ alcohol)[PVA]$$

$$n \ CH_2 = CH_2 \qquad \underline{\underline{high \ temperature/high \ pressure}}_{catalyst} \qquad CH_2 - CH \qquad n$$

$$CH_2 - CH$$

Styrene	CH ₂ = CH	Polystyrene (Styre form) or styrone	Making food and drink containers, coolers, construction materials, mattresses e.t.c.
Acryonitrile	$CH_2 = CHCN$	Polyacrylonitrile	Fabrics, rugs e.t.c.
		(Acrilan)	
Vinyl acetate	$CH_2 = CHOCOCH_3$	Poly vinyl	Latex paint, coatings,
		acetate (PVA)	textiles, adhesives.

Emphasis: Structure of the polymer and its monomer.

Rules of writing monomers from polymers

Examine whether you are going to see the repeating units.

$$\downarrow$$
 CH = CHOCOCH₃ (Monomer)

2.
$$\frac{\left(\text{CH}_2 - \text{CH} = \text{C} - \text{CH}_2\right)}{\text{CH}_3} \text{n}$$
Polymer
$$\text{Monomer}$$

$$\text{CH}_2 = \text{CH C} = \text{CH}_2 \quad \text{(2-methyl buta-1, 3-diene)}$$

$$\text{CH}_3$$

HIGH DENSITY POLYTHENE AND LOW DENSITY POLYTHENE (HDPE & LDPE)

On the other hand, if ethene is polymerized giving branches, it will end up producing a low density polymer of 0.92g/mc and this polymer will be known as LDPE which is soft and flexible.

CONDENSATION POLYMERS

These are formed by splitting monomers to eliminate a small molecule which is usually H₂O. This reaction is known as condensation reaction.

The empirical formula of the polymer in condensation polymerization is not the same as that of a monomer.

Example:

i) Polyester (Dacron)

Are formed by reacting a carboxylic acid and an alcohol monomers to form a polyester and H₂O molecule. E.g.

Benzene-1, 4-dioic (Terathepthalic acid) and Ethane-1, 2-diol.

Uses of polyesters

- Used in making of textile fabrics.
- Making films, magnetic coated films using audio and video tapes.
- In heart/cardiac operations to replace some heart blood vessels because it is non toxic, inert and non inflammatory.

Other examples:

$$O = \begin{pmatrix} O & Cl \\ C & -C & -CH - CH_2 \end{pmatrix} \cap O$$
 Polymer Monomer

$$C = \begin{pmatrix} O & O \\ || & C \\ C - CH_2 & C - O - CH_2 - CH - CH_2 \end{pmatrix} \cap O$$

Monomer

2-phenyl propane -1, 3-diol.

ii) Lactic acid (2-hydroxy propanoic acid) polymer

Is a polymer made up of one monomer of 2-dydroxy propanoic acid which undergoes self condensation. The uses of this polymer are of great importance in surgery and stitching broken deep wounds.

The advantage is that the polymer threads get dissolved in the body.

n CH₃ CH - COOH
$$\longrightarrow$$
 O O + H₂O CH₃ O + H₂O

iii) Polyamides

These re polymers formed by condensing a dicarboxylic acid or carboxylic acid chloride with a diamine to form an amide bond or link.

Examples:

Ethane -1, 4-dicarboxylic acid Hexane -1, 6-diamine Ethane-1, 2- dioic

$$\begin{array}{c} O \ O \\ || \ || \ || \\ H_2N-(CH_2)_4 \ NH_2 + HO \ C \ C - OH \\ & \downarrow \\ H \ O \ O \\ || \ || \ O \\ N - (CH_2)_4 - N - C - C \ n \ O \ + \ H_2O \end{array}$$

Peptide or amide bond.

Other examples

i) **Nylon-6 6:**

Is a polymer of Hexane-1, 6-dioic or its acid chloride and Hexane-1, 6-diamine. It is called so because its monomers are made up of 6 carbon atoms each.

$$\begin{array}{c} O & O \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ || & || \\ |$$

Uses:

- Made of high quality fabric for the making of clothes.
- Used in parachutes.
- Used in military gear.

The advantage of nylon-6, 6 is that it has got a good tensile strength, H₂O repellant, however, it has got a disadvantage of burning easily when put on fire.

NATURAL POLYMERS

These are polymers not made by man.

Examples:

Cotton
Wool
Proteins (Polyamides)

Carbohydrates (Polysaccharide) Lipids (Polyesters)

Rubber

RUBBER

NATURAL RUBBER

Is a polymer of 2-methyl buta-1, 3-diene which is simply known as isoprene unit.

Natural rubber is obtained from the rubber tree. Naturally, the rubber tree polymerizes the isoprene units by linking carbon 1 and carbon 4 and this leaves a double bond between carbon 2 and carbon 3 which double bond is in a cis – configuration.

OR:

$$\begin{pmatrix}
CH_3 \\
H_2C - C = C - CH_2 \\
H
\end{pmatrix}_{n}$$

Natural rubber is weak due to a few cross linkages and therefore it is less elastic but it can be improved by the process called Vulcanization.

Definition:

Vulcanization is a process of making rubber, hard, tough and resistant to wearing so that it is made useful. This is done by cross linking monomers using disulphide bonds, S-S-bridge linkage.

When rubber is heated with sulphur, it forms S-S linkages which make it tough.

Natural rubber $CH_3 \qquad H$ $CH_2 \qquad CH_2 \qquad CH_2$ $CH_2 \qquad +S$ $CH_3 \qquad H \qquad CH_2 \qquad CH_3 \qquad H$ $C \qquad -C - CH_2 \qquad C$ $CH_2 \qquad | \qquad C \qquad CH_2 \qquad |$ $S \qquad S \qquad S \qquad S \qquad S$ $| \qquad | \qquad | \qquad |$ $S \qquad S \qquad S \qquad S \qquad S$ $| \qquad | \qquad | \qquad |$ $C \qquad -C - CH_2 \qquad C - C$ $CH_2 \qquad CH_2 \qquad CH_2 \qquad CH_2$ $C \qquad -C - CH_2 \qquad C - C$ $CH_2 \qquad CH_2 \qquad CH_2 \qquad CH_2$ $C \qquad -C - CH_2 \qquad C - C$ $CH_2 \qquad CH_2 \qquad CH_2 \qquad CH_2$ $C \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - CH_2 \qquad -C - C$ $CH_2 \qquad -C - C - CH_2 \qquad -C - C$

Vulcanized rubber is useful in the following ways:

- Manufacturing of carlyres
- Manufacture of balls, bags, shoe soles e.t.c.
- Used ion insulation e.t.c.

Synthetic rubber

The knowledge of composition and structure of rubber has given rise to synthetic rubber. This has made polymer by polymerizing elastomers to give rise to a copolymer which has got some properties of natural rubber.

One of the examples is:

Stfren buta-diene rubber (SBR) which is made by polymerizing buta-1, 3-diene and styrene.

n CH₂ = CH CH = CH₂ + n
$$\bigcirc$$
 CH = CH₂
buta -1, 3-diene Phenyl ethene \bigcirc CH₂ - CH = CH₂ - CH - CH₂ \bigcirc n

FATS AND OILS

- Triglycerides / trimesters
- Differences between the oils and fats
- Components of a triglyceride (glycerol and fatty acid)
- Saponification
- Additives of soap
- Properties of soap.

FATS AND OILS

Fats and oil are trimesters made from glycerol (propane-1, 2, 3-triol) and long chain carboxylic acids called fatty acids. The R – groups of the acids, which can be the same or different within the same molecule, can be saturated or unsaturated, i.e. they may contain one or more carbon-carbon double bonds.

COMMON FATTY ACIDS

Name	Number of carbon atom	s Formula
Saturated acids		
Butanoic	C_4	CH ₃ CH ₂ CO ₂ H
Lauric	C_{12}	$CH_3(CH_2)_{10}CO_2H$
Myristic	C_{14}	$CH_3(CH_2)_{12}CO_2H$
Palmitic	C_{16}	CH ₃ (CH ₂) ₁ 4CO ₂ H
Stearic	C_{18}	$CH_3(CH_2)_{16}CO_2H$
Unsaturated acids	s	
Oleic	C_{18}	$CH_3(CH_2)_7CH=CH(CH_2)_7CO_2H$
Linolenic	C_{18} $CH_3CH_2CH=$	CHCH ₂ CH=CHCH ₂ CH=CH(CH ₂) ₇ CO ₂ H

A fatty acid – R group may be unsaturated, monounsaturated or polyunsaturated, depending on whether one or more double bonds is present.

TRIGLYCERIDES (Triesters)

Common fats and oils made of a glycerol and fatty acids (act as components). Triglycerides consist of three fatty acids and one glycerol.

FATTY ACIDS AND GLYCEROL

(Components of a triglyceride)

GLYCEROL

Is a polyhydric alcohol made up of three carbon atoms and 3 hydroxyl groups. It is therefore a small molecule.

FATTY ACIDS

A fatty acid is a long carbon chain molecule consisting of a carboxylic acid group at one end. The long carbon chain makes it to be hydrophobic and the carboxylic acid group makes it to be hydrophilic.

i.e.
$$CH_2$$
 CH_2 CH_2 $COOH$ Hydrophilic group

 H_3C CH_2 CH_2 CH_2

Hydrophobic tail (group)

If there are no double bond in the hydrocarbon chain, then the fatty acid is said to be *saturated fatty acid*.

Example: Stearic acid (Octadecanoic acid)

CH₃(CH₂)₁₆COOH

Started fatty acids from straight chains and their physical state is largely solid at room temperature because of their high melting points.

On the other hand, fatty acids that have got one or more double bonds within the hydrocarbon chain are said to be *unsaturated fatty acids*.

Example:

Oleic acid (Octadec-cis-a-enoic acid) C_{18} – [CH₃(CH₂)₇CH = CH(CH₂)₇CO₂H]

The presence of a double bond in the hydrocarbon chain results into the formation of a bend, which prevents the molecules from close packing resulting into the fatty acids having low melting points.

Those with trans double bond will tend to have fairly straight or linear carbon chain and the molecules will closely pack easily with high melting points making them solids at room temperature.

Fatty acids with more than one double bond are called **polyunsaturated fatty** acids (PUFAS).

Example: Linolenic acid – C₁₈.

↓

CH₃CH₂CH=CHCH₂CH=CHCH₂CH=CH(CH₂)₇CO₂H

SPONIFICATION

Saponification is the process of making soap.

SOAPS AND DETERGENTS SOAP

Soap is sodium or potassium salt of long chain carboxylic acids obtained by boiling fat or oil with NaOH or KOH solution.

MANUFACTURE OF SOAP

Oil or fat is put on a pan, sodium hydroxide solution is added and the mixture boiled.

Sodium chloride (Common salt) is added to precipitate out the soap a process known as salting out. Soap precipitates out as a hard cake.

It is then removed and processed into various shapes. Perfumes and dyes are also added to add value to the soap.

$$CH_2 - O - C - R$$

$$CH_2 - O - H$$

$$CH - O - C - R + 3NaOH \longrightarrow CH - O - H + 3R C - \overline{0}Na^+$$

$$CH_2 - O - C - R$$

$$CH_2 - O - H$$

SOURCES OF OILS

i) Vegetable oils:

These can be obtained from cotton seeds, sunflower, simsim, castor, groundnuts e.t.c.

In extraction of vegetable oil after removing the husks, the seeds are then crushed in power form and then boiled with H₂O for some time. The oil floats on top of the H₂O.

ii) Animal oil:

These are esters obtained from animals e.g. from whale, fish (sardines) and lard oil.

SOURCES OF FATS:

i) Vegetable fats:

Are obtained from plants like coconut or palm trees.

ii) Animal fats:

Are obtained from animals e.g. butter from milk and lard.

Uses of fats and oils

- Are used for food.
- In the manufacture of soap, candles and hair oils.
- In the manufacture of paints and vanishes.
- Ground nut oil is used to make vegetable ghee.

DISADVANTAGES OF USING ORDINARY SOAP

Soap forms scum with hard H_2O . Hard H_2O contains dissolved Ca^{2+} or Mg^{2+} which reacts with soap forming insoluble Ca^{2+} salt called scum.

$$\begin{array}{c} O \\ | \\ 2 \ R \ C \ ONa_{(aq)} + Ca^{2+} \end{array} \longrightarrow (RCO\overline{0})_2 Ca^{2+}_{(s)} \ + \ 2Na^+_{(aq)}$$

$$\begin{tabular}{l} O \\ 1 \\ 2 C_{17} H_{35} C ONa_{(aq)} + Ca^{2+}{}_{(aq)} & \longrightarrow & (C_{17} H_{35} COO)_2 Ca^{2+}{}_{(s)} + 2Na^{+}{}_{(aq)} \\ \end{tabular}$$

Formation of scum is expensive in that much soap has to be used to produce enough later for washing.

It also stains clothes.

THE CLEANING ACTION OF SOAP

A molecule of soap contains a water loving part which is polar $CO\overline{O}$ called hydrophilic part and the non polar ware insoluble (dirt soluble) part R – CH_2 called the hydrophocic part.

During washing, these molecules are dispersed and they form a spherical cluster around grease or dirt called micelle with the polar end attracted by H₂O. The dirt combines with the hydrophobic part while H₂O dissolves in the hydrophilic part.

As H₂O molecules attract the polar end, the surface tension of H₂O is lowered. Repulsion between the polar end of soap and rinsing help remove the dirt.

DETERGENTS

Synthetic detergents solve the problem of scum formation.

Synthetic detergents are surface active agents and are called "soapless soaps."

Like soap, detergents contain both hydrophilic (H₂O soluble) and hydrophobic (oil solution) parts.

An example of a detergent is alkyl benzene sulphonates i.e.

$$CH_3 - (CH_2)_n - CH_2$$
 - $SO_3^-Na^+$

However, the major disadvantage of alky benzene sulphonate detergents it that, they contain so many branches which are non-biodegrable and this can be dangerous if re-supplied into drinking H₂O.

This can be solved by making detergents with no branching (i.e. linear alkyl group).

TYPES OF DETERGENTS

i) CATIONIC DETERGENTS

These carry positive heads e.g. hexadecyl trimethyl ammonium bromide. They are made by reacting amines with alkyl halides.

They are used in making air conditioners.

Example:

 $C_{15}H_{31}CH_2NH_2 - Br + 3CH_3Br \longrightarrow C_{15}H_{31}CH_2^+N$ (CH₃) $Br^- + 2HBr$ In H_2O it behaves as;

$$C_{15}H_{31}CH_2^+N (CH_3) Br^- \longrightarrow C_{15}H_{31}CH_2^+N(CH_3)_3 + Br^-$$

ii) ANIONIC DETERGENTS

These carry negative heads. They are made from benzene by alkylation, sulphonation and neutralization reaction e.g. sodium-4-dodecyl benzene sulphonate.

These are used in the manufacture of both pastes and shampoos.

Anionic detergents can also be made from straight chain alcohol (C_{10} – C_{14})

iii) NON-IONIC DETERGENTS

These are neutral in H_2O i.e. the head carries no charge i.e. they are not dissociated e.g. $CH_3(CH_2)_{10}CH_2$ – $(OCH_2CH_2)_8$ –OH, ethoxylate made from long chain alcohols with ethoxides.

Example:

$$CH_3(CH_2)_{10}CH_2$$
-OH + $8CH_2CH_2$ \longrightarrow $CH_3(CH_2)_{10}(OCH_2CH_3)_8$ -OH

They are used as liquid detergents.

The action of detergents can be improved by addition of the following which constitute the bulk of the detergents.

- a) **Inorganic phosphates:** Are added to soaps to remove any soluble Ca^{2+} or Mg^{2+} in H_2O as Ca^{2+} or $Mg^{2+}PO_4^{3-}$.
- b) **Sodium peroxoborate:** This is added to act as a bleaching agent. They make clothes appear bright. They release H₂O₂ in H₂O which bleaches.
- c) Sodium sulphate: This is added mainly to increase the bulk of the powder.

Note:

- i) The major disadvantage of detergents containing phosphates is that they cause pollution in rivers, dams, and lakes. (Phosphates are used as food by algae so their presence promote the growth of algae causing foaming of H₂O thus polluting it.
- ii) Detergents are better than soaps because the can be used in any type of H₂O i.e. there is no formation of scum.
